This muscle in the Pelobatide has retained its embryonic relations to the larynx, and has only in a very slight degree acquired the secondary relation to the thyrohyal. Precisely the same thing is figured by Ridewood for *Xenopus* and *Pipa*. The long extension backwards of the esophageal muscle, universally characteristic of the Pelobatide (as far as our information goes), and its relation to the pelvis is possibly to be compared with the also very largely developed and apparently corresponding muscle in the Aglossa.

5. Microlepidoptera of Tenerife. By the Right Hon. LORD WALSINGHAM, M.A., LL.D., F.R.S., F.Z.S.

[Received November 12, 1907.]

(Plates LI-LIII, and Text-figures 241-243.)

In the Annalen of the K.-k. Naturhistorische Hofmuseum (Vienna) Professor Dr. H. Rebel has published a series of very interesting and instructive papers on the Lepidopterous Fauna of the Canary Islands; I desire now to record the result of a short visit to Tenerife, during which I was able to devote a good deal of attention to the Microlepidoptera of the island: a large proportion of these having been bred, it is satisfactory to be able to add some information upon their food-plants and larval habits. In the last of the papers above referred to, published in Vienna in 1906, Prof. Rebel gives a revised systematic catalogue and enumerates 87 species of Microlepidoptera (10 of which are merely indicated without special names under the genera to which they belong), 4 out of the remaining 77 not being recorded from Tenerife; we have therefore a residue of 73 species, to which the additions following in this paper may now be made, raising the total to 173 species (of which 70 are here described) distributed among 84 genera (seven of which are new). It is proposed to add some critical notes upon Rebel's List, where these seem to be required through the acquisition of additional information: the species not met with are merely inserted to facilitate reference.

I desire to express my very grateful thanks to Dr. George Perez, and to Dr. O. Burchard, for the great assistance they gave me in naming many plants which I should otherwise have been at a loss to determine; as also to the Rev. A. E. Eaton for numerous additions to my cabinet included in this paper.

I had moreover the great advantage of being allowed to examine Mr. W. W. White's collection at Guimar, enabling me more fully to appreciate the value of Dr. Rebel's work; nor can I forget that that author had already most kindly dealt with some material originally submitted to him from my collection. Without the encouragement offered by the complete and systematic manner in

which he undertook and continued his studies I could scarcely yet have ventured to work out my present collection.

In addition to the species named in the following pages a few others may be usefully indicated with a view to their identification by future collectors. I have still a number of living larvae in swelled shoots of Lycium afrum, collected at Puerto Orotava on April 27th. They are white with black heads, and were found on two only of several bushes growing along the narrow track leading eastward from the town along the middle of the rocky, abrupt slopes overhanging the sea. They feed in the interior of the base of the long thorn-like shoots which arise from the main branches, at some distance from the stem, causing them to swell perceptibly, but not distorting them. (Writing on September 1st: "None have yet changed to pupae, some have died.")

A larva found at Guimar on April 1st was very long and attenuated, of an ivory-white colour, burrowing along the pith in the interior of a stem of Salvia canariensis: this larva was alive a

few days ago, but showed no sign of feeding or pupating.

Another larva, which gave me several days of fruitless work, mines the minute leaflets of *Plocama pendula*, hollowing them out, and leaving them white and transparent—a condition in which they rapidly become shrivelled, when all trace of the larval work is lost, except the little brown desiccated point of the leaflets. I found unmistakable traces at Santa Cruz, in January, at the Barranco di Honda, between Santa Cruz and Guimar, in February, and again in a small barranco, close to Guimar, in March, where I secured, at last, one living larva. It was of a very pale amberyellow, and might have been a *Nepticula*; I failed to rear it.

A larva (possibly a *Phycid*) burrowing under the woolly clothing of the stems of *Phagnalon saxatile* is very abundant at Guimar, and was collected at sundry intervals during my stay there in March and April, producing only repeated disappointment.

During my visit to Tenerife a considerable number of Macro-lepidoptera were collected which have been placed in the hands of others more competent than myself to deal with them; it may, however, be interesting to mention that I bred a specimen of Eucrostis simonyi Rbl. (= Omphacodes *divincta Holt-White, nec Wkr.), Geometridae Stgr-Rbl. I. 2899, from a conspicuous red larva found on Frankenia ericifolia on the coast near Guimar, 6. III, excl. 15. IV. 1907.

I. PTEROPHORINA.

Being of opinion that in Entomology "A special type must be a zoological entity in its imaginal form" (Merton Rules, 36), on which text a sermon has yet to be preached, I find myself unable to regard as of generic value embryonic characters unsupported

by imaginal differences, and thus obliged to discard no small portion of the generic nomenclature of Vol. V. of Mr. Tutt's 'British Lepidoptera.'

I. PTEROPHORIDAE.

1. (207) BUCKLERIA Tutt.

=*Trichoptilus Meyr.; Stgr-Rbl. (nec Wlsm.).

I adopt Tutt's geneonym here as I entirely agree with him in separating paludum Z. and siceliota Z. from the Californian pygmaeus Wlsm., the type of Trichoptilus Wlsm., which has the fissure of the fore wings differently shaped, the lobes being more divergent.

Hab. S. and C. EUROPE. WC. ASIA. Canaries ³⁻⁶—TENERIFE: Guimar, 25. III − 14. IV., \bigoplus Andryala pinnatifida, 9-25. III, excl. 7. IV − 3. V. 1907; Puerto Orotava, 27. IV − 3. V. 1907 (Wlsm.); Forest de la Mina, 8. IV. 1894 (Eaton); La Laguna, 21. V. 1889 (Krauss) ³.

Prof. Rebel [Ánn. KK. Hofmus. VII. 262–3 (1892)] records Oxyptilus laetus from Tenerife, La Palma, and Gran Canaria; he subsequently [Ann. KK. Hofmus. IX. 81 (1894)] records a single

specimen from Tenerife as O. distans, suggesting that it may be a spring form of his Canarian laetus, and in Standinger and Rebel's Catalog (II. 1314) he treats laetus plus distans as two broods under one special name. In his last paper [Ann. KK. Hofmus. XXI. 43 (1906)] he retains both names, possibly through being unable to refer to the single specimen which he had recorded as laetus.

I found larvae at Guimar, feeding in March on the crowns of young plants of Andryala pinnatifida, completely covering themselves with the woolly débris of the consumed leaves; these produced up to the beginning of May typical forms of Oxyptilus distans, which I have compared satisfactorily with the actual types described by Zeller from Syracuse. They are, to all appearance, similar to all that I have previously bred from flowers and leaves of Andryala sinuata at Cannes and elsewhere. I have preserved specimens of the larvae for comparison with others from Europe.

Pterophorus laetus Z. Isis **1847**. 903 no. 442 ¹. Pterophorus (Oxyptilus) laetus Z. Lin. Ent. VI. 346 no. 11 (1852) ². Oxyptilus laetus Rbl. Ann. KK. Hofmus. Crombrugghia laetus Tutt Br. Lp. V. 459–60 (1906) ⁷.

Hab. S. EUROPE. WC. ASIA. N. AFRICA. Canaries ³⁻⁷—LA PALMA, 25. VIII. 1889 (Simony) ³—TENERIFE: Bajomar, 25. V. 1907 (WIsm.); 10. VIII. 1889 (Simony) ³—GRAN CANARIA: Bco. de los Chorros (San Mateo), 1. VIII. 1890; Mogan, Bco. de

los Hornos (Mogan), 4-20. VIII. 1890 (Simony) 3.

The only examples apparently agreeing with Zeller's type of Oxyptilus lactus were met with at Bajomar, on the sea-coast, where they were easily disturbed from flowering plants of Andryala pinnatifida; I brought home only three specimens. some full boxes being lost in my hurry to return to a waiting conveyance. These specimens are uniformly characterised by their slightly smaller size, by the lighter brown, rather than greyish, shade of the forewings, and by the notably bronzy brown tint of the hindwings, not to be found in my series of distans from the higher elevations. Tutt (Br. Lp. V. 450-1, 454-9) very strongly contends that there are two distinct species under the above names, and certainly seems to prove his case, but except perhaps by a careful examination of the genital segments, not yet undertaken, I confess to being unable to distinguish them with certainty through an extensive series, bred and captured from many remote localities. It seems indeed quite possible that these Tenerife specimens, obviously attached to the same plant, but at different dates and altitudes, may represent successive broods rather than truly distinct species. I suggest this without in any way disputing Mr. Tutt's conclusions, founded as they

are on differences in the genital segments, and on Dr. Chapman's very critical and careful study of the different larvae.

3. (209) PLATYPTILIA Hb.

3. (1339) Platyptilia (Amblyptilia Hb.) acanthodactyla Hb.

Alucita acanthodactyla Hb. Smlg. Eur. Schm. IX. Pl. 5 · 23-4 (1812?) ¹. Pterophorus acanthodactylus Stn. Ann-Mag. NH. (3 s.). III. 214 (1859) ². Platyptilia acanthodactyla Wlsm. Tr. Ent. Soc. I must point out that I adopt this name for the Tenerife species in the same sense as it is used by Zeller, and Rebel, and not as referring to *punctidactyla* Hw., being at present unable to agree with Tutt (l. c. 3) in his interpretation of Hübner's figures 23-24, and 35-36 respectively.

4, (210) ALUCITA L.

= ACIPTILIA Hb.; PTEROPHORUS Meyr. HB. Br. Lp. 435 (1895).

4. (1356·1) Alucita bystropogonis, sp. n. (Plate LI. fig. 2.)

Antennae brownish grey. Palpi short, slender, porrect; brownish grey. Head and Thorax brownish grey, the latter becoming hoary grey posteriorly. Forewings brownish grey, the fissure extending approximately to half the wing-length; the apical lobe shows two narrow, elongate, smoky blackish cloud-spots on its costal margin, one about the middle of the lobe, the other half-way between this and the base of the fissure; between them the costa is white, and beyond them the lobe is white, with a small black dorsal spot before the apex; the tornal lobe is white, from the base of the fissure to its apex, its costal cilia white on the basal half and smoky black on the distal half of the lobe; the dorsal cilia of the apical lobe whitish beyond the fissure to two-thirds, thence smoky black below the apex; the dorsal cilia of the tornal lobe whitish, with a black spot a little before the middle of the lobe, their tips

slightly grey-shaded. Exp. al. 16-20 mm. Hindwings brownish grey; cilia slightly paler throughout, especially along their base on the dorsum of the tornal lobe. Abdomen brownish grey, with slender white lines along either side of the dorsum. Legs white, with smoky black patches at the base of each pair of white spurs.

 $Type \ \ (98768); \ \ \ \ (98769); \ \ \ \ \ (98801) \ Mus. \ Wlsm.$

Hab. TENERIFE: Forest de la Mina, 7. IV. 1904 (Eaton); Guimar, ⊕ Bystropogon plumosus, 28. III, excl. 4. IV − 29. V. 1907 (Wlsm.); La Laguna, 23. IV. 1907 (Wlsm.). Forty-three

specimens.

Some varieties assume a decidedly browner tint than the type, and in these the white cilia are often so modified by the extension of the brown suffusion, especially within and below the fissure, as to alter considerably the general appearance of the insect: there are several intermediate degrees of such modification in a bred series.

The larva feeds on Bystropogon plumosus, drawing together the leaves and young flower-buds on the leading shoots; it attains a length of 11 mm., and is very pale glancous green, covered with short and somewhat spatulate hairs, among which longer diverging hairs, arising each from a minute brownish pimple, are ranged in groups along either side of a faint greyish dorsal shade and along the spiracular line; the head is very pale amber-brown. The pupa, which has a line of elongate black spots along the dorsum, is covered with scattered groups of hairs of varying length, the shorter ones not spatulate as in the larva. It is attached posteriorly to the leaf of its food-plant without any encircling band.

I received this insect first from the Rev. A. E. Eaton, taken in the Forest of La Mina, and lately found it abundant above Guimar, but, like its food-plant, it is somewhat local. It reminds one closely of *Gypsochares baptodactyla Z.*, and is very similarly coloured, but the lobes of the hindwings are more slender and the fissure of the forewings somewhat deeper. There is a very noticeable difference also in the pupa: that of *Gypsochares baptodactyla* has a line of conspicuous elongate black spots on either side of the dorsum, whereas the pupa of *bystropogonis* has but one mediodorsal line of spots.

5. (1365·1) Alucita particiliata, sp. n. (Plate LI. fig. 3.)

=*Aciptilia tetradactyla Rbl. Ann. KK. Hofmus. VII. 263, 280 no. 39 (1892): XXI. 43 no. 177 (1906).

Antennae white, speckled above with brownish grey. Palpi porrect, slender; whitish, with a dark spot at the base of the terminal joint, which extends a little beyond an obtuse short frontal tuft. Head and Thorax brownish ochreous. Forewings brownish ochreous at the base, blending to pale straw-whitish beyond; costa narrowly smoky blackish, this colour suffusing the whole of the costal cilia, except about the extreme apex; the

fissure extends to a little more than the wing-length; the cilia of the tornal lobe, and of the lower margin of the apical lobe, distinctly straw-white on their basal half and smoky blackish on their outer half (this distinct division in the basal and distal colouring of the cilia is in itself amply and uniformly sufficient to separate particiliata from tetradactyla L., in which the cilia are darkened throughout). Exp. al. 20–22 mm. Hindwings brownish ochreous; cilia of all the lobes smoky fuscous on their costal margins, whereas on their dorsal margins the basal two-thirds are straw-white, the distal third only fuscous. Abdomen whitish, especially at the base, with a narrow dorsal, and wider lateral brownish grey lines. Legs white.

Type 3 (98810); 9 (98816) Mus. Wlsm.

Hab. TENERIFE: Santa Cruz, 23. XII - 12. II. 1907; Puerto

Orotava, 21. IV. 1907. Fifteen specimens.

Having mistaken this species in the field for tetradactyla L., no special search for the larva was undertaken, but I strongly suspect that two green and slightly hairy larvae found on Larandula abrotanoides at Santa Cruz, which I unfortunately failed to rear, must

have belonged to it.

Rebel records worn specimens of Aciptilia tetradactyla from Pedro Gil (Tenerife, 1600 m., 30. VII. 1889—Simony), and from Gran Canaria (Richter). As Pedro Gil is on very high ground the date is not surprising, but it is at least probable that these specimens (which I have not seen) belong to the same species which occurs so abundantly at Santa Cruz in January and February, and of which I have a single specimen taken at Puerto Orotava on April 21st. I certainly thought the species was tetradactyla when I took it, indeed I should have secured more specimens had I then recognised it as new.

6. (1365.2) Alucita hesperidella, sp. n.

Antennae pale brown, speckled with white. Palpi short, porrect, slender, scarcely projecting beyond the face; pale brown. Head and Thorax pale buff-brown. Forewings pale buff-brown, the costa narrowly white, more conspicuously before the apex, a small, oblique, inverted darker greyish streak a little beyond the middle (sometimes obsolete); the fissure extends approximately to half the wing-length, the tornal lobe being white along its upper half from the base of the fissure to its apex, the cilia tinged with brownish grey, as also are those of the apical lobe. Exp. al. 16–18 mm. Hindwings pale greyish brown; cilia the same, becoming whitish at the apex of the tornal lobe. Abdomen pale greyish brown, with whitish dorsal line. Legs white, a slender greyish line along their outer sides.

Type \circ (98825); \circ (98827); \oplus (98829) Mus. Wlsm.

Hab. TENERIFE: IV. 1884 (Leech); Santa Cruz, 13-31. I. 1907 (W7sm.); Guimar, 21. III. 1904 (Eaton), 2. III - 14. IV. 1907, ⊕ Micromeria varia, 23. III, excl. 16-26. IV. 1907 (W7sm.); Puerto

Orotava, 27. IV - 8. V. 1907 (Wlsm.); La Laguna, 23. V. 1907 (Wlsm.); Tacaronte, 31. V. 1907 (Wlsm.). Fifty-nine specimens. Common at Guimar, Santa Cruz, Orotava, etc. The larva is

Text-fig. 241.

Alucita hesperidella (98829).

slightly hairy, the hairs arranged in small divergent fascicules; it is of a dull glaucous green, with narrow, parallel, paler dorsal and spiracular lines; head pale brown; it tapers slightly toward the anal segments; all the legs uniformly of the same colour as the body. It feeds on the leaves of *Micromeria varia*, from which it is not difficult to sweep or beat it into the net.

The species greatly resembles Gypsochares olbiadactyla Mill., to

which it is precisely similar in the distribution of the white margins. Some specimens are distinguishable by the possession of a costal spot, but the uniformly more slender apical lobe of the forewings at once distinguishes it from the more robust Gypsochares which in other respects it might almost be said to mimic. Many years ago I received two specimens from the late Mr. J. H. Leech, which stood in my cabinet as doubtfully distinct from olbiadactyla until I bred that species.

Prof. Rebel described his Gypsochares hedemanni from specimens

collected at Orotava in April; I found the same quite abundant in the larval stage on *Phagnalon saxatile* at Santa Cruz and Guimar, and saw traces of it in other localities where its food-plant occurs. Many years ago Millière gave me a specimen of his *olbiadactylus*, taken in the Estérel (vide Nat. Sic. V. 224): I was therefore well-acquainted with his species, which I have taken in Spain and reared from *Phagnalon rupestre* there. Millière figures and describes the larva and pupa, but he omits to mention whether he actually bred or captured the imago. He suggests that the larvae feed on lichens growing on the rocks where they were found, but he adds that they did not eat in captivity, and quickly pupated. I know that *Phagnalon saxatile* is common in the locality where he discovered the species, and where I have myself searched for it unsuccessfully when in ignorance of its food-plant. His figure of the larva shows no black dorsal spots, nor does he describe them.

Text-fig. 242.

Gypsochares olbiadactyla (98902).

but the Tenerife larvae (and, if I rightly remember, the Spanish larvae also) possessed a line of such spots, one on each segment. It is open to doubt whether the larvae recorded by Millière on rocks were not those of Alucita tetradactyla L., which is abundant on the same spot. After very careful comparison of specimens with Millière's figure, and with the exponent received from him there remains no possible doubt that Gypsochares hede-

manni as figured and described by Rebel, and represented by a named specimen in Mr. W. W. White's collection, is the same as Pterophorus olbiadactylus Mill. I have received the same species from Spain from Dr. Staudinger under the logonym "leptodactyla." The traces of the larva are easily recognised by the curling-back of the woolly underside of the leaves from which it has eaten the upper surface and parenchyma, thus exhibiting small white spots distributed about the plants on which it has fed: this is similar to the effect produced by larvae of Alucita adamas Cnst., on Staehelinus—a noticeable sign of its presence, to which I called my late friend's attention before he was himself acquainted with the larva, and before we had either of us seen the imago.

Hab. Germany. Austria. **Canaries**—Tenerife: IV. 1884 (*Leech*); Santa Cruz. ⊕ *Inula viscosa*, 10. I, excl. 24. I – 14. II., 29. IV. 1907 (*Wlsm.*); Guimar, 13. III – 10. IV., ⊕ *Inula viscosa*, III, excl. 23. III – 7. IV. 1907 (*Wlsm.*); Puerto Orotava, 29. IV – 4. V. 1907 (*Wlsm.*); La Laguna, 23. V. 1907 (*Wlsm.*).

Prof. Rebel records an "unbestimbares Fragment" of a species of Leioptilus from Guimar, 16. V. 1889 (Krauss); this was probably inulae Z., which is common and widely distributed in Tenerife. It seems to occur wherever Inula viscosa is abundant, as at Guimar, Santa Cruz, Puerto Orotava, etc.—I bred specimens from larvae boring the leading shoots; they were easily distinguished by their dull glaucous green colour, and by a conspicuous series of blackish dorsal spots.

10. (1395·1) Ртекорнокия (Lioptilus) меlanoschisma, sp. n. (Plate LI. fig. 1.)

Antennae smoky bone-colour. Palpi slender, porrect, projecting less than the length of the head beyond it; smoky fuscous above, pale beneath. Head smoky fuscous; face straw-whitish. Thorax pale, or sometimes brownish, straw-colour. Forewings pale straw, sometimes darker brownish straw—in both cases fading somewhat on the dorsal half; a very narrow fuscous line along the costa to two-thirds from the base; the fissure extends to two-fifths of the wing-length; the cilia within the fissure are uniformly fuscous, connected with a dark fuscous spot at the base of the fissure, which is distinctly visible on the underside; the dorsal cilia are also fuscous. Exp. al. 16-17 mm. Hindwings and cilia brownish

grey, the surface of the lobes somewhat shining. Abdomen concolorous with the hindwings. Legs straw-white, or straw-brownish, unspotted.

Type 3 (98934); 9 (98935) Mus. Wlsm.

Hab. TENERIFE: Santa Cruz, 21. I = 9. II., \bigoplus Phagnalon saxatile, 31. I, excl. 27-29. III. 1907; Guimar, 12. III. 07; Puerto Oro-

tava, 29. IV. 07. Seven specimens.

The larva feeds in the flowers of *Phagnalon savatile*, but the species is not abundant. It is closely allied to *pectodactylus* Stgr. (=*chrysocomae* Rgt.), but differs especially in the darkened cilia of the fissure reaching fully to the base; these are very conspicuous.

7. (215) STENOPTILIA Hb.

11. (1406) Stenoptilia (Adkinia Tutt) bipunctidactyla Sc.

Phalaena bipunctidactyla Sc. Ent. Carn. 257 no. 673 (1763)¹. Pterophorus (Pterophorus Z.) serotinus Z. Lin. Ent. VI. 361-4 no. 27 (1852)². Mimaeseoptilus serotinus Rbl. Ann. KK. Hofmus. Hab. EUROPE. WC. ASIA. N. AFRICA. Canaries— TENERIFE ³⁻⁶: 2. VIII. 1889 (Simony)³; Santa Cruz, 8–16. II. 1907 (W7sm.); Guimar, 14. III − 12. IV. 1907 (W7sm.); Puerto Orotava, 4. V. 1907 (W7sm.); La Laguna, ⊕ *Bartsia tricago*,

12. VI, excl. 1. VII. 1907 (Wlsm.).

Common at Santa Cruz, Guimar, and Orotava. Two specimens were bred on July 1st from larvae found feeding on Bartsia trixago, at La Laguna, on June 12th. These larvae were noted as pale green, with purplish dorsal line; with groups of hair distributed evenly on each segment, and with minute black tubercular spots above the spiracles: they agreed well with Tutt's description of the larva of bipunctidactyla (Br. Lp. V. 350), to which species I have no doubt the Tenerife specimens are rightly referred.

II. AGDISTIDAE.

8. (216) AGDISTIS Hb.

Rebel records only two species, tamaricis Z. and canariensus Rbl.; I am now able to add frankeniae Z., salsolae sp. n., and staticis Mill.

12. (1420) Agdistis frankeniae Z.

Adactyla frankeniae Z. Isis 1847. 900–2 no. 439 ¹. Agdistis frankeniae Z. Lin. Ent. VI. 321 no. 1 (1852) ²: Stgr-Rbl. Cat. Lp. Pal. II. 77 no. 1420 (1901) ³; Chpm. & Tutt Br. Lp. V. 128–30, 131–2 (1906) ⁴; Wlsm. Ent. Rec. XIX. 53–5 (1907) ⁵.

Hab. S. EUROPE 1-5—Sicily 1. Corsica: Punta Parata, 5. V.

1896 (II/sm.). Spain: Cadiz: Chiclana, ⊕ Frankenia pulverulenta, 27. I, excl. 2. II. 1901 (II/sm.). N. AFRICA — Algeria: Biskra, Hammam-es-Salahin, 5. III – 2. IV. 1903, 14. V. 1903, ⊕ Frankenia, 10-22. III, excl. 13. III. 1906, 19. III – 23. IV. 1903 (III. 23. IV. 1903 (III. 23. IV. 1903 (III. 23. IV. 1904 (III. 24. IV. 1907 (III. 1907, ⊕ Frankenia ericifolia, 6. III. excl. 6-24. IV. 1907 (II/sm.); Puerto Orotava, 11. III. 1904 (Eaton), 21. IV – 14. V. 1907 (II/sm.); Tejina, 18. III. 1902 (Eaton); Bajomar, 25. V.

1907 (Wlsm.).

This is very common on the coast on Frankenia ericifolia and possibly on other species of the genus; the larvae are extremely similar to those of what I must (pace Tutt) regard as the very closely allied Agdistis (Ernestia Tutt) lerinensis Mill., but, like the perfect insects, considerably smaller. Although variable in size the Tenerife specimens agree better with Zeller's original types from Sicily than with the uniformly larger specimens which I found at Biskra (Algeria). I took and bred many specimens, including a single example at light at Guimar, 1200 ft. above the sea-level, at which alone its food-plant grows.

13. (1420·1) Agdistis salsolae, sp. u.

Antennae stone-grey, a dark spot on the basal joint. Palpi very short, the median joint rough, hoary grey; terminal joint blackish, not projecting beyond the frontal clothing. Head and Thorax hoary stone-grey. Forewings hoary stone-grey, minutely speckled with black, except on the more thinly clothed, slaty grey, triangular fold-space; the outer third of the costa narrowly white, showing four strong, black, oblique spots, the apex of the wing also black, including the apical cilia; on the lower edge of the fold-space are two strong, elongate, black spots, preceded by a smaller one at the angle of the fold, and followed by another, more conspicuous, and including the cilia at the tornus, before the base of which it is produced upward along the termen; terminal cilia grevish white, a slender blackish line along their middle. Exp. al. 16-18 mm. Hindwings slaty grey, with some black speckling on their lower half; cilia whitish grey, a slender shade-line along their middle. Abdomen brownish grey, with slender white dorsal and lateral lines. Legs, posterior pair white, thickly sprinkled with greyish fuscous scales—less thickly on the anterior extremities of the joints.

Type 3 (98356) Mus. Wlsm.

Hab. Tenerife: Puerto Orotava,

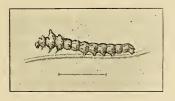

Salsola oppositifolia, 30.

IV - VI, excl. 5. VI - 16. VII. 1907. Six specimens.

The larva is yellowish brown, varying to grey-brown (precisely the colour of dead leaves and stalks of the food-plant); it has a group of four small tubercular excrescences on the prothorax, followed by two much larger and more elevated humps on the mesothorax, each tipped with a black spot; a much shorter pair, also black-tipped, and rather wider apart on the metathorax; on

the first abdominal somite are four black dots in two pairs, one

Text-fig. 243.

Agdistis salsolae (98418).

behind the other, while on the anterior half of the remaining somites are some more or less strongly indicated slender, blackish, oblique lateral lines; the ninth abdominal somite with two short black protuberances above. Type \bigoplus (98418) Mus. Wlsm.

This larva differs in structure from others of the genus, and especially by its much higher metathoracic humps from that of *frankeniae* Z., although in

the image the two species can scarcely be distinguished.

Agdistis salsolae is more easily recognised by a glance at the underside than in any other way, for here frankeniae shows only some rather obscure spots on its dull costa, the tornal and apical shades being also insignificant, whereas in salsolae the white costa of the forewings shows very clearly on the underside, making the four costal spots very distinct; the apical and tornal patches in the cilia are also very clear, and the limbus of the hindwings is thickly sprinkled with black scales, a raised brush of the same along the cubitus. In salsolae the legs are also somewhat stouter and more distinctly mottled, while scarcely any trace is shown of the subcostal spot at the end of the plical space which is always to be found in frankeniae; the spots are also usually larger and more conspicuous, but in bred specimens of both species this is scarcely a reliable character.

The larva is extremely difficult to rear, and I was successful with only six out of some sixty collected.

14. (1425) Agdistis canariensis Rbl.

Agdistis canariensis Rbl. Ann. KK. Hofmus, XI. 114–5, 146 no. 148 (1896) ¹: XIII. 380 no. 161 (1899) ²; XXI. 36, 43 no. 181 (1906) ³: Stgr-Rbl, Cat. Lp. Pal. II. 78 no. 1425 (1901) ⁴.

Hab. Canaries ¹⁻⁴ — Tenerife ¹⁻⁴: Santa Cruz, 3. V. 1895 (Hedemann)¹; Puerto Orotava, 20. IV – 3. V. 1907 (Wlsm.). FUERTEVENTURA ³: 15. V. 1905 (Polatzek) ³.

I have but little to add to what has been already published: a specimen in Mr. White's collection is probably correct, and exhibits the white unspotted costa, beyond the middle of the forewing, specially noted in the original description, and sufficing to separate this from others of the genus. I had at first regarded it as probably a mere variety of some other species, but the distinguishing character is very clearly shown in a specimen (98415) taken at Puerto Orotava, 3. V. 1907, which can only be compared with the nearly allied adactyla Hb.

I met with a single small larva (98417) at Guimar, on March 11th, on Phagnalon saxatile, the flowers of which it continued to eat very sparingly until it died on May 25th: persistent efforts to find other specimens were unsuccessful. The brownish larva, less than 4 inch in length, has a pair of small projecting pronotal tubercules, and a metanotal pair, larger and more erect, also an anal tubercule; on all the segments are short, reflexed, bristles, arising from pairs of small tubercular excrescences. It differs somewhat from the larva of the allied satanas Mill., and I had regarded it as probably that of adactyla Hb., with which I am not personally acquainted, until observing the close alliance of the imago of canariensis Rbl. to that species. There can be little doubt that this was the larva of canariensis, although I so unfortunately failed to rear it.

(1426) Agdistis satanas Mill.

Agdistis satanas Mill. Bull. Soc. Ent. Fr. XLIV. (5 s. V: 1875). p. clxvii (1875) 1; Cat. Lp. Alp-Mar. 377-8. Pl. 2 · 9 (1875) 2: Nat. Sic. V. 221-2 no. 3114 bis (1886) 3: Stgr-Rbl. Cat. Lp. Pal. II. 78 no. 1426 (1901) 4; WIsm. Ent. Rec. XIX. 53 (1907) 5.

Hab. S. France ¹⁻⁵: Cannes, ⊕ Scabiosa candicans VI, excl. VII ⁴. In Mr. Tutt's recently published 'British Lepidoptera' [V. 129, 136 (1906)] some doubt is expressed as to whether a larva which I submitted to Dr. Chapman as that of Agdistis satanas Mill. is really an Agdistis at all: this opportunity may be taken to record the evidence upon which the identification rests. My experience in attempting to rear canariensis was precisely similar to that of Millière, and the failure may seabably be attributed to the hisporating publis of the larvae of this groun coming probably be attributed to the hibernating habits of the larvae of this group coming into premature practice through the necessity of keeping the bottles containing them in a comparatively cool temperature. I extract the following abridged notes from my voluminous correspondence with my late friend Monsieur Millière:—In 1885 Millière had two larvae which he believed to be those of Agdistic satanas. He was taking great care of them-one disappeared, the other fixed itself up for pupation, taking great care of thein—one disappeared, the other fixed itself up for pupation, but did not change, drying up, but preserving its form, so that he could figure it. In his letter to me, of August 19th, 1885, he mentions this fact and adds "car je crois avoir acquis la preuve que c'est bien la chenille de Satanas." The proof appears in the following translation: 'One female of this Agdistis has had the good thought to lay ten fertile eggs, but I have not been able to feed the little caterpillars, which have not touched anything and have died of hunger. I have preserved in spirit some of these young larvae, which, under a strong lens, seem to me to have all the characters of the caterpillar which you have prepared for your collection. I can send you these larvae obtained ab ovo.' I have empty egg-shells, sent at that time, but cannot find the larvae in spirit.

In June 1886 Millière published (Nat. Sic. V. 221-2) the following additional

information on Agdistis satanas :-

"Obs. Au dernier moment je trouve à l'habitat de la Satanas, la chenille de cette Agdistis qui, du 15 au 25 juin, est parvenue à son entier développement. Elle se nourrit sur la Scabiosa candicans dont elle ronge les feuilles, et sans doute sur d'autres plantes sous-ligneuses.

"Cette larve rappelle la chenille de sa congénère Heydenii, mais elle est plus courte, avec les caroncules dorsales moins développés et les poils longs et raides, dont elle est couverte, dépourvus, à l'extrémité, du petit renflement spatulifère qu'on remarque

chez sa voisine.

"L'état léthargique dure à peine un mois.

"L'Agd. Satanas qui n'a qu'une génération pond rarement en captivité, cependent une ♀ enfermée en un tube de verre, ayant pondu une 30° d'œufs, j'ai pu les étudier. Ces œufs sont relativement gros, elliptiques, blanchâtres, et profondement cannelés en long; leur éclosion eut lieu 15 jours après.

"La jeune ch. se montre alors à peu près ce qu'elle sera à ses divers âges. Elle

passe l'hiver fixée à une tige sèche, dissimulée dans les brindilles herbacées.'

15. (1428) Agdistis (Herbertia Tutt) tamaricis Z.

Hab. S. EUROPE ^{1-2, 8}. WC. ASIA ⁵. AFRICA—EGYPT: Alexandria ⁴—Algeria ¹⁰: Biskra, Hammam-es-Salahin, 6. III − 28. IV. 1903, 3. IV. 1904, ⊕ *Tamariv*, 9. III, excl. 10. IV. 1904 (*Wlsm.*). Canaries ⁶⁻⁸—Tenerife: Santa Cruz, 30. IV. 1898 (*Hintz*) ⁶; ⊕ *Tamariv gallica*, 14. I, excl. 27. II − 8. IV. 1907, ⊕ 24. V, excl. 13-15. VI. 1907 (*Wlsm.*). Cape de Verdes: St. Vincent ^{3, 5-6, 10}.

Abundant in many parts of the Island, and no doubt thus widely distributed owing to the prevailing custom of planting Tamarix along the sides of the main roads so far as these extend. Preserved larvae compared with European and Algerian specimens show a curious modification in form, the tuberculous excrescences on the prothorax and mesothorax, and on the second, fifth, and ninth abdominal somites, although similarly placed, are distinctly exaggerated, being at least one-third longer than in European specimens, a peculiarity in which they are at least closely approached by larvae from Algeria. I am unable to find any difference in the imago.

16. (1430) Agdistis (Adactylus Crt.) staticis Mill.

Agdistis staticis Mill. Bull. Soc. Ent. Fr. XLIV. (5 s. V: 1875). p. clxvii (1875)¹: Cat. Lp. Alp-Mar. 375-6. Pl. 2 · 4-8 (1875)²: Wlsm. Ent. Mo. Mag. XXVII. 141 (1891)³; Stgr-Rbl. Cat. Lp. Pal. II. 78 no. 1430 (1901)⁴. Adactylus staticis Chpm. & Tutt Br. Lp. V. 128-30 (1906)⁵. Agdistis staticis Wlsm. Ent. Rec. XIX. 53-4 (1907)⁶.

Hab. S. France ¹⁻⁶: Ile Ste Marguerite ¹⁻²; Beaulieu ³; ⊕ Statice cordata, III, excl. 15. V. 1890 ³; ⊕ V, excl. VIII ¹⁻². Algeria ⁶: Ain-Oumash ⁶, Biskra ⁶, Hammam-es-Salahin ⁶, ⊕ Statice limonium ⁶, 2. III − 5. IV, excl. 28. IV. 1903, 23. III − 13. VI. 1906 (Wlsm.). Canaries—Tenerife: Puerto Orotava, ⊕ Statice pectinata, 8. V, excl. 29. V − 13. VI. 1907 (Wlsm.).

The moths bred at Puerto Orotava from larvae on Statice pectinata are of a distinctly darker shade than those from Cannes and Biskra, but perhaps this may be partially due to fading in the

older specimens; the larvae are similar.

The larvae of *lerinensis* Mill. could not be found among those of *staticis* as they were at Cannes and Biskra.

II. ORNEODINA.

I. ORNEODIDAE.

Hab. EUROPE 1-3. Canaries 4—Tenerife: Guimar (W. W.

White) 4.

Prof. Rebel records hübneri from Guimar on the authority of Sir George Hampson. My only knowledge of this species in Tenerife is derived from specimens in Mr. White's collection.

III. TINEINA.

I. GELECHIADAE.

10. (297) METZNERIA Z.

18. (2487·1) Metzneria insignificans, sp. n.

Antennae snow-white, faintly annulate with greyish fuscous. Palpi moderately recurved, the median joint somewhat coarsely scaled, but scarcely roughened beneath; stone-whitish, sprinkled with fawn-brown and greyish fuscous. Head and Thorax stone-whitish, sprinkled with fawn-brown. Forewings stone-whitish, profusely sprinkled with pale fawn-brown and pale greyish fuscous scales; there is a faint indication of a small spot at the end of the cell, preceded by another in the middle of the wing, and the line of the fold is sometimes slightly tinted with ochreous; cilia speckled as on the wing-surface, and with a scarcely perceptible oblique shade-line before their tips. Exp. al. 10–11 mm. Hind-wings iridescent pale bluish grey, with rosy reflections; cilia very pale brownish cinereous. Abdomen iridescent, bluish grey. Legs pale brownish cinereous.

Type & (14145) Mus. Wlsm.

Hab. Tenerife: Guimar, 1700 ft., 20. III. 1904 (Eaton); Santa Cruz, 3. IV. 1904 (Eaton). Two specimens.

I did not meet with this species.

19. (2488·1) Metzneria infelix, sp. n.

Antennae stone-whitish, faintly annulate with greyish fuscous. Palpi stone-whitish, shaded with fuscous along their outer sides. Head and Thorax stone-whitish, sprinkled with fawn-grey. Forewings stone-whitish, with a slight ochreous tinge, freely sprinkled with fawn-grey, especially along the costa, along the upper edge

of the outer end of the fold, and about the termen; a small fuscous spot in the fold, scarcely before the middle of the wing, is followed by a larger more elongate discal spot, scarcely beyond the middle, another lying at the end of the cell; a few of the scales along the termen are tipped with fuscous, a slight sprinkling also occurring along the middle of the greyish ochreous cilia. Exp. al. 11-15 mm. Hindwings pale bluish grey; cilia pale greyish ochreous. Abdomen fawn-grey; anal tuft stone-whitish. Legs stone-whitish.

Type 3 (98962) Mus. Wlsm.

Hab. TENERIFE: Santa Cruz, 8-14 II. 1907; Puerto Orotava, 23. IV, 10. V. 1907. Five specimens, but only one in good condition.

This species differs from tristella Rbl. in having the antennae annulate, and in the paler colour of its somewhat narrow forewings; moreover, although the spots are in the same position they are unaccompanied in this species by the yellowish, or ochreous, streaks which in tristella tend to connect and emphasise them. The palpi appear to be also a little more slender.

20. (2489.1) Metzneria dichroa, sp. n. (Plate LI. fig. 4.)

Antennae whitish ochreous, speckled with black above. Palpi whitish ochreous, more brownish ochreous on their outer sides. Head whitish ochreous. Thorax pale ochreous. *Forewings* whitish ochreous, longitudinally smeared with pale brownish ochreous below, above, and beyond the cell; an elongate black discal spot lies on the middle of the wing, followed by a smaller one at the end of the cell and preceded by two, even less conspicuous, groups of black scales on the fold and at the upper edge of the cell respectively; cilia whitish ochreous, with a slender brownish line running through their middle. Exp. al. 14-16 mm. Hindwings tawny grey; cilia pale brownish ochreous. Abdomen shining, pale grevish. *Legs* whitish ochreous. *Type* 3 (98304) Mus. Wlsm.

Hab. Tenerife: Villa Orotava, \oplus in seed-heads of Carlina salicifolia, 25. IV - 7. VII, excl. 3. VI - 18. VII. 1907. Four

specimens.

Larva white, without markings. Head olivaceous blackish, rather broadly edged with white on either side of the suture; pronotal plate indistinct, pale olivaceous. Long. 6 mm. $Type \bigoplus$ (98308: 7. VII.) Mus. Wlsm.

Bred from larvae, collected April 25th, feeding in old seedheads of Carlina salicifolia Cav. in barrancos above Villa Orotova.

Allied to castiliella Mschl.

21. (2490·1) Metzneria monochroa, sp. n. (Plate LI. fig. 5.)

Antennae pale ochreous. Palpi ochreous; brownish ochreous on their outer sides. Head and Thorax pale ochrous, slightly

smeared with pale brownish ochreous. Forewings whitish ochreous, suffused with very pale brownish ochreous, leaving the neuration faintly indicated by slender lines of the paler ground-colour, scarcely noticeable, except towards the apex; a slight suffusion of fawn-brown from the base of the costa reaches to about one-third, with a group of scales, indicating a spot, below the costa near its termination; a plical spot is placed below and a little beyond this, and there is also a similar fawn-brown spot, rather more conspicuous, at the end of the cell; cilia pale ochreous, with a very faint dividing shade-line. Exp. al. 23 mm. Hindwings tawny grey; cilia very pale brownish ochreous. Abdomen grey. Legs pale ochreous; tarsi unspotted.

Type ♂ (98309); ♀ (98310) Mus. Wlsm.

Hab. TENERIFE: La Laguna, 11. V. 1907. Two specimens. The ♂ in fine condition, the ♀ not quite so good; found below the large leaves of wild Artichoke (Cynara cardunculus), sheltering on the ground from a high wind. It is near torridella Mn., but much paler and quite distinct.

11, (321) SITOTROGA Hnm.

Taken at Santa Cruz, and on board ship when coming home.

12. (3201) PRAGMATODES, gn. n.

(πραγματώδηs=troublesome.)
Type Pragmatodes fruticosella Wlsm.

Antennae $\frac{4}{5}$, slightly serrate, somewhat thickened in δ ; basal joint without pecten. Maxillary Palpi very short, connivent. Labial Palpi recurved, moderate, median joint smoothly scaled; terminal joint shorter than median. Haustellum moderate. Head and Thorax smooth. Forewings elongate, gradually tapering to apex: neuration 12 veins; 7 and 8 stalked, to costa, 6 out of 7; rest separate, 1 furcate at base. Hindwings (-1), costa and dorsum almost parallel, apex strongly produced, termen oblique;

cilia 3, costal cilia somewhat bristly towards base: neuration 8 veins; 2 to 5 remote; 6 and 7 stalked, 6 weak. Abdomen moderate. Legs, hind tibiæ clothed with loose hairs.

I am unable to refer this somewhat obscure species to any described genus. In the combined characters 3 and 4 remote, 6 and 7 stalked in the hindwings; and 6 out of 7, beyond its furcation with 8, in the forewings, this agrees with Sitotroga Hnm., which however differs in having a pecten on the basal joint of the antennae. Schistophila Chrét. and Glauce Chmb. differ in having broader hindwings, with 3 somewhat approximated to 4, and the latter has long, flattened, broad, black subcostal bristles. Ptocheuusa Hnm. has 3 and 4 of the hindwings connate, and 3 and 4 of the forewings coincident. The group of Aproaerema-Drnt., having 6 and 7 of the hindwings stalked, differs in having 3 and 4 connate; Apodia Hnm. agrees with Pragmatodes in the neuration of the forewings, but like other allies of Aristotelia Hb., with 3 and 4 of the hindwings remote, differs in having 6 and 7 separate, not stalked.

23. (2901·1) Pragmatodes fruticosella, sp. n. (Plate LI. fig. 10.)

Poecilia (Stenolechia) sp. Rbl. Ann. KK. Hofmus, XI, 128, 146 no. 192 (1896) 1. Stenolechia (Poecilia) sp. Rbl. Ann. KK. Hofmus. XXI, 44 no. 214 (1906) ².

Antennae dirty whitish, obscurely annulate with fuscous. Palpi dirty whitish, dusted with fuscous, a black band before the apex on the median and terminal joints. Head and Thorax whitish, speckled with fuscous. Forewings dirty stone-whitish, dusted with fuscous; a basal patch, with convex outer margin, reaches to nearly one-fifth from the base and is thickly bestrewn with fuscous, the space beyond it forming a narrow fascia of the pale ground-colour, followed by a transverse blackish band, also irregularly convex, but ill-defined on its outer side; this again is followed along the dorsum and costa by somewhat profuse blackish dusting, a small dark discal spot lying in the middle of the wing; beyond the middle an inverted and rather angulated fascia of the pale ground-colour is ill-defined and followed by profuse blackish speckling, reaching to the apex and termen; cilia pale brownish grey, with a shade-line before their outer ends. Exp. al. 6.5-7.5 mm. Hindwings deeply sinuate, but not squarely excised below the apex; grey; cilia pale brownish grey. Abdomen greyish. Legs pale brownish grey, with fuscous bands on tibiae and tarsi.

Type ♀ (98969); ♂ (98970) Mus. Wlsm. *Hab.* Tenerife: Santa Cruz. 31. I – 21. II, 29. V. 1907, ⊕ Rubia fruticosa, 13. II, excl. 19-20. III. 1907; Guimar, 28. II - 4.

III. 1907. Ten specimens.

Bred in March from larvae found mining the leaves of Rubia fruticosa in February. The moth was also taken on the wing from January to March, and in May, at Santa Cruz and Guimar.

I feel very little doubt that the *Poecilia* (Stenolechia) sp., which Rebel described from a worn \mathfrak{P} , taken by von Hedemann, in a barranco near Santa Cruz among Tamarix, 5. V. 1895, was the species now described as fruticosella, the larvae of which, although difficult to rear, are very common on Rubia in all the barrancos west of the town.

13. (320) APODIA Hnm.

24. (2900.4) Apodia guimarensis, sp. n. (Plate LI. fig. 6.)

Antennae cinereous. Palpi whitish cirereous. Head and Thorax whitish cinereous, the latter with a pale fawn-brown patch above. Forewings pale fawn-brown, with whitish cinereous lines and streaks, placed longitudinally and obliquely, but not transversely; one along the costa from base to apex, one along the cell from the base, branching to the costa beyond the middle, and again before the apex; another along the upper edge of the fold as far as the middle of the wing, nearly touching the outer end of an oblique dorsal patch arising before the middle, a similar patch arising before the tornus and angulated outward toward the apex; cilia whitish cinereous, dusted with fawn-brown scales on their basal half. Exp. al. 7:5-9 mm. Hindwings pale grey; cilia pale brownish cinereous. Abdomen brownish grey. Legs pale cinereous.

Type 3 (98979) Mus. Wlsm.

Hab. Tenerife: Guimar, 13-28. III. 1907 (Wlsm.), 20. III. 1904 (Eaton). Four specimens.

14. (310) ARISTOTELIA ${ m Hb}.$

25. (2797·1) Aristotelia ancillula, sp. n.

Antennae pale fawn, broadly barred with dark fuscous above, almost obliterating the paler colour, except a noticeable spot at the outer end of the basal joint. Palpi pale cinereous; the median joint coarsely clothed beneath, speckled externally with fuscous; terminal joint much sprinkled with fuscous externally. Head rosy fawn, shaded with fuscous. Thorax rosy fawn, a strong dark fuscous shade anteriorly between the tegulae. Forewings rosy fawn, thickly sprinkled with fuscous, and with some dark fuscous, almost black, spots—one on the costa near the base, another, larger, on the dorsum below it, and a smaller one between them—these more or less confluent; opposite the middle spot is a larger one at about one-sixth, its lower edge resting on the fold; again, a little before the middle, is a similar spot on the disc, more or less confluent with a smaller one slightly preceding it on the fold, and these again are followed by a smaller and less conspicuous spot at the end of the cell; cilia rosy fawn, sprinkled with fuscous along their base. Exp. al. 13 mm. Hindwings (1); shining, somewhat iridescent, pale bluish grey; cilia fawnbrownish. Abdomen greyish. Legs pale fawn-ochreous, somewhat speckled with pale fuscous.

Type $\c 98982$) Mus. Wlsm.

Hab. TENERIFE: Guimar, 25. III. 1907. Unique.

Agreeing precisely in the form of the hindwing with servella Z., but differing from this, and so far as I am aware from all other species of the genus, in the form and distribution of the more or less distinct spots.

26. (2811.1) Aristotelia cacomicra, sp. n.

Antennae brownish grey. Palpi with the median joint slightly ruffled beneath; pale cinereous, dusted with brownish grey, with a fuscous band around the middle of the terminal point. Head and Thorax brownish grey. Forewings brownish grey, with a slight sprinkling of pale cinereous scales, some of which about the apex are tipped with brownish fuscous; three brownish fuscous spots are indistinctly indicated, one on the middle of the fold, one before the outer end of the fold, and one above and between these, on the cell, forming with them an almost equilateral triangle; cilia brownish cinereous. Exp. al. 7–8 mm. Hindwings iridescent, dark bluish grey; cilia brownish cinereous. Abdomen greyish fuscous. Legs brownish cinereous, the tarsi spotted whitish at the joints.

Type & (98983) Mus. Wlsm.

Hab. Tenerife: Santa Cruz, 26. I - 21. II. 1907, 29. IV. 1907;

Puerto Orotava, 14. V. 1907. Seven specimens.

Near rumicetella Hfm., but without any indication of pale opposite spots before the apex; also differing noticeably in the absence of the shade-line which runs through the cilia in that species, and gives a rounded appearance to the otherwise almost evenly pointed wing.

15. (319) CHRYSOPORA Clms.

27. (2894·1) Chrysopora Boseae, sp. n. (Plate LI. fig. 7.)

Antennae golden yellow, annulate with black. Palpi black, medial and terminal joints tipped with yellow. Head shining, brassy yellowish. Thorax black, with a few yellow scales. Forewings black; a bright golden fascia, at one-fourth from the base, descends obliquely inward from costa to dorsum, and is followed on the middle of the dorsum by two yellow spots, the first preceded by some raised black scales and having at its upper edge a tinge of coppery chestnut which is repeated in a strong spot at the end of the cell, above and beyond which is a triangular pale yellow spot on the costa; cilia pale brownish ochreous, thickly sprinkled, except on their outer ends, with black. Exp. al. 7–8 mm. Hindwings deeply excised below the apex; grey; cilia brownish grey, a slender pale cinereous line marking their base. Abdomen

blackish. Legs black, with pale ochreous spurs; hind tarsi with about five pale ochreous annulations.

Type 3 (98991); 9 (98992) Mus. Wlsm.

Hab. Tenerife: Puerto Orotava, 27. IV - 8. V. 1907, ⊕ mining leaves of Bosea yervamora, 21. IV, excl. 11-29. V. 1907. Thirty

specimens.

The larva makes blotch-like mines in the leaves of *Bosea yervamora*, an indigenous shrub (which also occurs in the West Indies), on which it is by no means uncommon at Orotava; probably to be found elsewhere, as I believe I recognised the old mines between La Laguna and Tegeste.

V. 1907 (Wlsm.); Bajomar, 25. V. 1907 (Wlsm.).

Stainton [Ann-Mag. NH. (3 s.). III. 213] recorded *anthyllidella Hb. from Porto Santo (Madeiras), and described elachistella, sp. n., from Northern Deserta (Madeiras). In 1894 (l. c. 6) I referred Stainton's supposed *anthyllidella to *albipalpella HS., and recorded as the same species a single specimen (13617) from Madeira. Rebel (l. c. 7) suggests the possibility that the species recorded by me as *albipalpella HS. (=*anthyllidella Stn.) might be the species which he proceeds to describe as infestella Rbl. I think this extremely probable, so far as the specimen from Madeira (13617) is concerned for I have now before me more reliable exponents of albipalpella HS., and this Madeiran specimen does not completely agree with them; but it does agree with psoralella Mill., which Rebel (l. c. 10) sinks as a synonym of the true anthyllidella Hb. As we are all seeking for the truth, and as

one good turn deserves another, may I, in thanking Prof. Rebel for the hint, suggest that his infestella is psoralella Mill.? In support of this theory, without seeing Rebei's type, I can only say that psoralella Mill. is very common on Psoralea bituminosa in Tenerife, and the larvae from which I reared it there are the same as those pointed out to me by Millière himself at Cannes many years ago. Rebel's specimens of infestella were taken at Orotava 14–30. IV. 1895; I have specimens of psoralella labelled Orotava, 26. IV – 14. V. 1907.

In any case I must admit that the Madeira specimen (13617) is psoralella Mill., while Stainton's specimen from Porto Santo, recorded as *anthyllidella (no. XXVIII) has a white face and white palpi, and is a finer specimen of elachistella Stn. than is the unset type (no. XXIX, σ) from Northern Deserta.

Hab. Madeiras 2-6.—Northern Deserta: (Wollaston) 2-3-5.—Porto Santo: (Wollaston) 1. Canaries—Gran Canaries.—Gran Canaries.—Stainton [Ann-Mag, NH. (3 s.), III, 213] recorded *anthyllidella Hb. from Porto Santo, and described elachistella, sp. n., from Northern Deserta. In 1894 (l. c. 4) I referred Stainton's supposed *anthyllidella to *albipalpella HS., and recorded as the same species a single specimen (13617) from Madeira. Having now before me more reliable evponents of albipanctella HS., I find that this specimen from Madeira does not completely agree with them; but it does agree with psoralella Mill., which I have bred from Psoralea bituminosa at Cannes and in Tenerife. I have again examined Stainton's specimens and find that his *anthyllidella from Porto Santo (no. XXVIII) has white palpi and white face, and is a finer specimen of elachisizlla Stn. than is the unset type (no. XXIX, 3) from Northern Deserta. I took two specimens of this species at Las Palmas on June 15th. The locality "Mad." (Stgr-Rbl. Cat. Lp. Pal. II. 153 no. 2835) pertains to elachistella Stn. (=*anthyllidella Stn.)—the true anthyllidella Hb. has not yet been recognised as occurring in the Madeiras or Canaries.

29. (2847.01) Aproaerema genistae, sp. n. (Plate LI. fig. 8.)

Antennae black, with white annulations. Palpi white, with a slender black line along the under side of the acute terminal joint. Head white. Thorax brownish olivaceous. Forewings pale brownish olivaceous at the base, blending to blackish about the middle, and on the dorsum nearly to the base; beyond the middle is a straight, well-defined, oblique white fascia, of even width, pointing slightly outward from dorsum to costa; beyond it the terminal portion of the wing is profusely sprinkled with some brownish, many blackish, and a few elongate shining steely grey scales, the latter prevailing around the margin and at the base of the tawny greyish cilia. Exp. al. 8 mm. Hindwings leaden grey; cilia tawny grey. Abdomen leaden grey. Legs white, with broad tawny fuscous bands around the hind tibiae. Type $\mathfrak{P}(98993)$; $\mathfrak{F}(98994)$ Mus. Wlsm.

Hab. TENERIFE: La Laguna, ⊕ in shoots of Genista canariensis, 18. V, excl. 21. V - 9. VI. 1907. Thirty-three specimens. Closely allied to captivella HS. and acanthyllidis Wlsm. [Ent. Mo. Mag. XLI. 40 (1905)], differing from the former in the white fascia being more outwardly oblique from dorsum to costa, and from the latter in the form of this fascia, which is consistently of even width throughout, throwing no projection toward the termen on its outer side; it is also slightly larger and has darker hindwings.

30. (2847·2) Aproaerema thaumalea Wlsm. (Plate LI. fig. 9.) Aproaerema thaumalea Wlsm. Ent. Mo. Mag. XLI. 41 no. 2847·2 (1905)¹.

Hab. Algeria : Hammain-es-Salahin, \bigoplus Astragalus gombo, III-V, excl. IV-VI. *Canaries—Tenerife: Guimar, \bigoplus Lotus sessilifolius, 6. III, 16-27. IV, excl. 10-29. IV, 20. V. 1907.

Thirteen specimens, bred from larvae forming sand-galleries beneath the trailing shoots of Lotus sessilifolius, on the coast near Puerto Guimar, are not in any way distinguishable from my Algerian specimens bred from Astragalus gombo. The foodplants are not very nearly allied, but they both grow on hot sandy soil, and the habits of the larvae are almost similar, but the larvae themselves, or at least the specimens which I preserved, believing them to belong to this species, are totally different, so much so that I am led to doubt whether the Algerian specimen (97110) does not rightly belong to some other species feeding on the same plant. About the Tenerife larva there can be no mistake: it is a curious, long, attenuated larva, with the thoracic somites slightly swelled; the head pale yellow-brown, pronota' plate broad, but very faintly indicated; abdominal claspers short almost rudimentary. It is creamy white, with a slender reddish line on either side of the dorsum, running from the mesothorax to the anal extremity. Long. 13 mm. \oplus (98996) Mus. Wlsm. It descends into the sand in a silken tube, coming up to feed on the leaves of the plant, and again retiring below ground. So far as I observed, the Algerian larva did not descend below the surface of the soil, the sand-tubes being among the trailing branches.

The specimen figured (98995, \mathfrak{P}) is from Guimar.

31. (2847·1) Aproaerema mercedella, sp. n. (Plate I.I. fig. 11.)

Antennae yellow, annulate with black. Palpi pale yellowish, the median joint black nearly to its apex, except a narrow line of white along its upper side; terminal joint with a broad blackish shade before its apex. Head yellowish white. Thorax pale yellowish, with a diffused greyish fuscous median shade above. Forewings blackish, with pale yellowish patches and lines occupying almost as much space as the ground-colour, which is accom-

panied, around their edges, by some rust-brown suffusion, especially noticeable on the apical portion of the wing; at the extreme base a short yellow streak, which follows the fold, is quickly diverted and dilated to the dorsum; a large pale yellow patch, commencing above its outer extremity on the costa, is attenuated obliquely outward along the cell, ending in a pale ocellate spot at the end of the cell, containing an elongate black dot, a little beyond which an outwardly angulate, narrow, pale yellow fascia crosses the wing; this is produced at either extremity along the margins and around the apex, forming thus a narrow yellowish band enclosing a space of the shape of a blunt arrow-head; cilia pale yellowish, with two parallel black lines running through them and emphasising the obtusely rounded appearance of the apex; the pale costal patch throws a slight excrescence across the fold before the middle, but does not reach the dorsum. Exp. al. 10 mm. Hindwings leaden grey; cilia brownish grey. Abdomen grey; anal tuft ochreous. Legs ochreous, the tarsi banded with leaden grey. *Type* ♂ (14107) Mus. Wlsm.

Hab. Tenerife: Las Mercedes, ⊕ on dead moss-grown bark of Laurocerasus lusitanica, 7. III, excl. 24. VIII. 1904 (Eaton).

Unique.

Among described species this is most nearly allied to nigrato-mella Clms. and concinusella Chmb., from both of which it differs in the presence of dark dorsal markings; the pattern is found also in other allied American genera. A single specimen was bred by the Rev. A. E. Eaton from a larva found on dead moss-grown bark of Laurocerasus lusitanica, 7. III., near the Casa del Agua, in the forest of Las Mercedes, 2050 ft. (near La Laguna), on August 24th, 1904.

33. (2749·1) Telphusa schizogynae, sp. n. (Plate LI. fig. 12.)

Antennae black, dotted with white throughout. Palpi, terminal joint longer than the smoothly and compactly clothed median; pinkish white, with two slender black lines running throughout the length of the terminal, and a black patch on the outer side of the median joint at its base. Head iridescent, steely Thorax black, shaded with brownish ochreous at the sides. Forewings steely whitish, suffused with bluish grey to two-thirds from the base, and again narrowly around the apex; at the extreme base is a short brownish ochreous patch, externally bounded by a black dorsal streak, and separated from the costa by black; there are two black discal spots, one before the middle, one at the end of the cell—the first of these preceded by a similar spot on the fold below it; the outer edge of the blue-grey shading is straight, except for the outer discal spot projecting through it; apex and cilia white, the latter with a faint median shade. Exp. al. 14-16 mm. Hindwings abruptly and deeply excised below apex, veins 3 and 4 separate, 5 approximate to 4, discoidal weak, 6 and 7 stalked; tawny grey; cilia paler, with a lighter line along their base. Abdomen and Legs tawny grey, the tarsi pale-spotted.

Type of (98997); 9 (98998) Mus. Wlsm.

Hab. Tenerife: Puerto Orotava, \oplus in galls on stems of Schizogyne sericea, 21. IV – 16. V, excl. 25. IV, 10–30. V, 3–30.

VI, 2-10. VII, 19. VIII. 1907. Fourteen specimens.

A distinct species, perhaps most resembling fugitivella Z. + lyellella Crt., but larger. The median joint of the palpi is too smooth to be described as "thickened with rough scales beneath," but the clothing of this joint is variable in the genus Telphusa. Bred from larvae feeding in a swelling on the stems of Schizogyne sericea: these galls are abundant on the plant, but their numbers are likely to be somewhat misleading as to the abundance of the species, for not only are they for the most part empty galls belonging to many previous seasons, but a very large proportion of the living larvae are affected by parasites—indeed I have been able to rear only fourteen specimens from at least 150 galls collected.

34. (2749.2) Telphusa canariensis, sp. n. (Plate LI. fig. 15.)

Antennae mealy white, annulate with fuscous. Palpi mealy white, with two blackish annulations on the terminal joint, and two oblique blackish bars on the outer side of the median. Head and Thorax mealy white, the latter slightly sprinkled with fuscous. Forewings mealy white, sprinkled, and almost suffused locally,

with greyish fuscous; an oblique costal spot, at one-sixth from the base, points downward to a similar one on the fold a little beyond it, which again points to another on the dorsum, each containing some raised scales, there is also a small spot at the extreme base of the fold; another costal spot occurs before the middle and is somewhat diffused outward and downward toward a small dark discal spot, beyond which, transversely placed, are two small spots at the end of the cell, these and the preceding being partially surrounded by pale ochreous scaling; there is a faint indication of a transverse shade beyond the end of the cell, throwing an acute angle outward towards the apex from below its middle, the space beyond this shade being of the paler groundcolour, but succeeded by more shady suffusion around the apex and termen; cilia mealy white, dusted with greyish fuscous. Exp. al. 16 mm. Hindwings pale grey; cilia pale brownish grey. Legs whitish ochreous. Abdomen brownish ochreous.

Type & (99000) Guimar, Mus. Wlsm.

I have already recorded this species from Madeira, and Prof. Rebel mentions a Tenerife specimen which I have seen in Mr. White's collection. I took a fine δ at Guimar on April 4th. These specimens have a salmony pink hue in the ground-colour of the forewings, which is wanting in European specimens. I have three specimens, taken in Algeria, which resemble the Canary form, and to which I had given the MS. name "salmonis": as all the markings correspond with those of English domestica Hw., it is perhaps sufficient to indicate these and the Canary and Madeiran specimens under this varietal name, taking my Guimar δ (99000) as the Type of this variety.

II. 1907, ⊕ Tamarix gallica, XII—I, excl. 20. II – 17. IV. 1907 (Wlsm.); Monte de Aguirre, 800 m., 21. VII. 1889 (Simony) 13 .

Among a series of fifteen specimens, bred from *Tamarix gallica*, near Santa Cruz, one pale variety approaches somewhat closely in colour to the Algerian *sinuatella*, Wlsm. [Ent. Mo. Mag. XL. 223 (1904)], but the form of the markings is distinctly that of

plutelliformis, which it resembles also in its smaller size.

The larva feeds on Tamarix gallica, in December and January,

the moth flying in January, February, and March.

Larva, somewhat attenuate to either extremity, greenish yellow, with reddish patches on the anterior portion of each segment, and a few, sparsely distributed, bristly hairs; there is a single black dot on either side of each thoracic somite. Head pale green; no distinguishable pronotal plate; legs and claspers long, blackish.

edge, is an elongate dark streak, also edged above with whitish; at the base is a black limbal streak which does not occur in plutelliformis. When describing siewersiellus, Christoph had before him (unwittingly) specimens of both plutelliformis and sieversi, both taken at Sarepta, and apparently both bred from Tamarix. His description of siewersiellus was obviously taken from plutelliformis, and Staudinger und Wocke (Cat. Lp. Eur. 290) give the synonymy correctly thus: 1831. sieversi Stgr.

1832. plutelliformis Stgr.; = olbiaëlla Mill.; = siewersiellus Chr.

Christoph's collection contains six specimens and a larva labelled "sieversi Stgr."; and four specimens labelled "plutelliformis Stgr." These are all from Sarepta, and are correctly determined, except that the third specimen of plutelliformis is a worn example of an allied species distinct from both. The name siewersiellus does not occur in the collection: the larva labelled "sieversi" appears to be distinct from, but closely allied to, that of plutelliformis (siewersiellus), and probably fed on Tamarix laxa or pallasii (vide Chr. l. c.).

Christoph on Tamarix laxa or pallasii (vide Chr. l. c.).

Christoph sent Zeller two specimens, which constitute Zeller's series of "plutelliformis Std sent Zener two specimens, when constitute Zener's series of "puteuti-formis Stdg." The first, received from Christoph in 1860, is labelled by Zeller "Gelechia plutelliformis Stdg. E. Z. 59, 239": this determination is incorrect, it is sieversi Stgr. The second specimen is not specially labelled, not being regarded as distinct from the first; it is, however, truly plutelliformis Stgr. (-sieversiellus Chr.). When describing sieversi, Staudinger observes that, owing to its similarity cm.). When describing sieversi, Staudinger observes that, owing to its similarity to plutelliformis, he had at first thought it that species, but, recognising its distinctness, he retains for it the name given by Christoph in honour of the now unfortunately deceased entomologist Sievers. It is therefore presumable that Christoph sent Standinger sieversi Stgr., labelled "sieversiellus Chr." On the other hand, Christoph sent Hofmann, in 1871, four specimens of "sieversiella Chr.", which are rightly determined by Hofmann as plutelliformis Stgr. In Standinger and Rebel's Catalog (II. 144) we find both species united thus:—2584. plutelliformis Stgr.; = olbiaëlla Mill.; = sieversiellus Chr.; = sieversi Stgr., ab.].

Stgr. [ab.]

The confusion caused by both species occurring at Sarepta, and both species being distributed by Christoph as "siewersiellus," has doubtless suggested the erroneous idea that the verbal variants Hypsolophus siewersiellus Chr. and Gelechia sieversi Stgr. pertained to mere varieties of one species. Standinger's two species are undoubtedly distinct, and we must revert to the synonymy of Standinger and Wocke's Catalog, correcting that of Staudinger and Rebel thus .-

37. (2611.2) Gelechia Lunariella, sp. n. (Plate LI. fig. 13.)

Antennae shortly biciliate in o; blackish, spotted with rosy reddish above. Palpi moderately biserrate beneath; rosy whitish, speckled and ringed with black, the terminal joint having a black ring before its middle, and a broader band before its minutely pale apex; the intermediate space pale rosy. Head steely greyish, with rosy iridescent scale-tips. Thorax black, mixed with rosy reddish. Forewings cinereous, varying to rosy reddish; sprinkled and suffused with tawny grey and black scaling, the latter for the most part slightly raised, and exhibited, especially on the base of the dorsum, in an outwardly oblique, narrow, partially interrupted, transverse fascia at about one-sixth from the base; in a patch on the middle of the cell, another, toward the end of the cell, produced downward to the dorsum at

the outer end of the fold; above it a blackish costal patch, preceded by an elongate costal shade, the intermediate spaces bright rosy red; the terminal portion of the wing is much mottled with similar colouring, tending to indicate marginal spots, radiating through the tawny greyish cilia, which have two narrow shade-lines running through them before their ends. Exp. al. 15–17 mm. Hindwings tawny grey, with a rosy tinge; cilia pale brownish cinereous. Abdomen and Legs brownish cinereous, the latter spotted externally with tawny fuscous.

Type 3 (99001); 9 (99002) Mus. Wlsm.

Hab. Tenerife: San Andres, \bigoplus Rumex lunarius, 23. I, excl. 27 II – 9. III. 1907; Guimar, \bigoplus 12. IV, excl. 11–24. V. 1907; Puerto Orotava, \bigoplus 24. IV, excl. 23. V. 1907. Thirteen specimens.

Bred from pale glaucous green larvae collected on Rumex lunarius in January and April; these larvae turned to rosy

reddish before pupating (99003 Mus. Wlsm.).

I met with this species first at San Andres, near Santa Cruz, and subsequently observed it near Guimar, and again at Orotava. It contorts and attaches together the young terminal leaves of its food-plant, and probably occurs wherever this indigenous shrub is to be found on the island. It is closely allied to nigrorosea Wlsm., but is a darker and rather broader winged insect: it is also very near to the European diffinis Hw.

38. (2635) Gelechia epithymella Stgr.

Gelechia epithymella Stgr. Stett. Ent. Ztg. XX. 242 no. 89 (1859)¹; Stn. Tin. S-Eur. 141, 150 no. 28, 332 (1869)². Lita epithymella Mill. Ic. Chen-Lp. III. 392–4. Pl. 149 · 8–10 (1874)³: Cat. Lp. Hab. S. France ³⁻⁶: Cannes ^{3, 4}, Monaco ³, Mentone ⁴, ⊕ Solanum nigrum, VIII–IX ³⁻⁵, excl. IX–XI ³⁻⁵—S. Spain ^{1-2, 5-6}: Chiclana, 14. III ¹⁻². Canaries—Tenerife: Puerto Orotava, ⊕ Hyoscyamus

albus, 10. V, excl. 6-16. VI. 1907 (Wlsm.).

After persistingly searching plants of *Hyoscyamus albus* in the expectation of finding *Gelechia hyoscyamella* Mill., I at last found larvae mining the leaves of two or three plants only, among several, in a lane east of Puerto Orotava. To my surprise these produced rather dark varieties of *Gelechia epithymella* Stgr., which has been recorded as feeding on *Solanum nigrum* in the south of France, but which has not hitherto been observed in Tenerife.

39. (2636·1) Gelechia micradelpha Wlsm.

Gelechia micradelpha Wlsm. Ent. Mo. Mag. XXXVI. 217–8 no. 1916·3 (1900) 1 ; Stgr-Rbl. Cat. Lp. Pal. II. 264 no. 2694^{ter} (1901) 2 .

Hab. S. France ¹⁻²: Perpignan, ⊕ Lycium europaeum, 22. V, excl. 7-9. VI. 1899 (W7sm.) ¹. Algeria: Biskia, 13. II - 7. IV. 1903, ⊕ Lycium europaeum, 12. I, excl. 6. III. 1904 (W7sm.): Hammam-es-Salahin, 22. III - 30. IV. 1904 (W7sm.). Canaries —Tenerife: Santa Cruz, 10. I. 1907 (W7sm.); Puerto Orotava, 27. IV. 1904 (W7sm.).

This obscure little species is common among Lycium afrum, west of Santa Cruz, and east of Orotava. It has not hitherto been known to occur in the Canaries, unless it be the same as the worn specimen, taken by von Hedemann at Orotava, 14. IV. 1895, recorded as Lita sp., by Rebel, Ann. KK. Hofmus. XI. 127, 146

no. 191 (1896): XXI. 44 no. 211 (1906).

40. (2712·1) Gelechia sciurella, sp. n. (Plate LI. fig. 14.)

Antennae dark grey, with blackish annulations. Palpi hoary, much sprinkled and suffused with black and chestnut-brown, except on the inner side of the median joint, which appears slightly serrate beneath. Head and Thorax steely grey. Forewings whitish grey, mottled, suffused, and blotched with chestnutbrown and black; the former prevailing especially along the costal area, from the base to beyond the middle, and in a diffused patch a little beyond the upper angle of the cell; the latter especially in a roundish spot on the fold near the base, in a large reniform patch before the middle, its lower edge crossing the fold, and in an inverted, upwardly attenuate, oblique patch resting on the outer end of the fold; the apex and termen are also speckled with black; cilia smoky greyish, with some pale brown around the apex. Exp. al. 10-12 mm. Hindwings subiridescent. bluish grey; cilia tawny grey. Abdomen grey. Legs greyish fuscous, pale cinereous at the joints.

Hab. Madeiras—Madeira: Funchal, 2600 ft., 8. III. 1902 (Eaton). Canaries—Tenerife: Guimar, 27. II - 12. IV. 1907

(Wlsm.); Arafo, 13. IV. 1907 (Wlsm.). Seven specimens.

Most nearly allied to *provinciella* Stn., but smaller and more glossy; the darker shades are greyer, and the ground-colour is more cinereous, less ochreous. I have had the type in my collection for some years: the capture of six worn specimens in Tenerife has induced me to describe it.

I bred a single specimen from a larva found at Puerto Orotava; this did not emerge until June 5th, although I captured five specimens on the same spot on May 10th, when I found the larva feeding on *Convolvulus althaeoides*: the food-plant of this species was hitherto unknown.

44. (2270·02) TRICHOTAPHE CONVOLVULI, sp. n. (Plate LI. fig. 16.)

= Ceratophora sp. Rbl. Ann. KK. Hofmus. VII. 275, 283 no. 58 (1892) 1. Brachmia (Ceratophora) sp. Rbl. Ann. KK. Hofmus. XXI. 44 no. 216 (1906) 2.

Antennae dark tawny fuscous. Palpi dull whitish ochreous, unspotted; the median joint clothed with closely appressed scales. Head whitish ochreous. Thorax dark tawny fuscous. Forewings dark tawny fuscous, with a small, narrow, elongate, pale ochreous costal spot at four-fifths from the base; on the cell, at one-third from the base, is an elongate blackish spot, followed by another at two-thirds—each rather obscurely annulate with chestnut-brown scales; a similar spot lies in the fold, straight below the first discal, and a row of minute ochreous spots precedes the dark tawny grey cilia. Exp. al. 13–15 mm. Hindwings brownish grey, with a slender pale ochreous line along the base of the otherwise unicolorous cilia. Abdomen fuscous. Legs dark tawny fuscous; the spurs and joints of the tarsi pale cinereous.

This species (which is obviously the same as Ceratophora sp. Rbl.) is closely allied to juncidella Clms., but differs in its darker face and palpi: the median joint of the palpi is more roughly scaled, and the pale costal spot is distinctly visible on the under

side of the forewings.

Hab. Canaries—Tenerife: Santa Cruz, 19-22. I. 1907, ⊕ Ipomoea quinquefolia, 19. I. excl. 20. II - 2. III. 1907 (Wlsm.).

—Gran Canaria: (Richter) 1-2. Thirty-two specimens.

Bred from larvae reminding one much of those of Brachmia rufescens Hw. in their black and white oblique striping. Head honey-yellowish. edged with blackish; pronotal plate honeyyellow, posteriorly broadly black-margined lunately, suture honey-yellow: mesothorax, metathorax, and abdominal somites I-II blackish, mesothorax conspicuously separated by white from the metathorax and prothorax, the latter similarly separated from the head; abdominal somites III-IX white, with blackish markings—the lateral markings are oblique, as in rufescens, but having no pale dorsal stripe to interrupt them, anteriorly above, they form on each segment a complete arcuate band, followed on somites III-VII by a transverse bar of the same colour, but on V this bar is not apparent, owing to dark dorsal suffusion; normal spots distinct, black; legs black, abdominal claspers tipped with blackish; long, 15 mm. (99006 Mus. Wlsm.). The larvae roll the leaves of Ipomoea quinquefolia in January, and are extremely abundant on this introduced plant at Santa Cruz, especially on a wall below the Quisisana Hotel.

V. 1907 (W7sm.).—Gran Canaria ^{5,10}: Las Palmas, 9. V. 1895 (Hedemann) ⁵.

Having placed this species in the Oecophoridae, through failing to observe that veins 6 and 7 of the hindwings were stalked, Prof. Rebel not unnaturally overlooked my genus Apatema (Gelechiadae, 1900), allied to Oecogenia (†Oegoconia) Stn., and Symmoca Hb.; and when describing mediopallidum, from Corsica, I overlooked the Madeiran Gelechia fasciata Stn., which I had erroneously referred to Hypatima Stgr-Wk. (nec Hb.) in 1894. The specimen which Stainton recorded as Oegoconia quadripuncta Hw., from the Jordan (9212 Mus. Wlsm.), is Apatema fasciata Stn.,

badly worn.

It should be observed that HYPATOPA Wlsm. Pr. US. Nat. Mus. XXXIII. 200, 211 (1907)=*Hypatima HS. (nec Hb.) type Oecophora inunctella Z., and that HYPATIMA Hb. (nec HS.)= Chelaria Hw.]

46. (3050·2) Apatema lucidum, sp. n. (Plate LII. fig. 3.)

Antennae greyish ochreous; basal joint black above. Palpi

pale ochreous, the median joint shaded on its basal half with black, and with a black spot on its distal half externally. Head and Thorax pale ochreous, the latter slightly shaded with fawnbrown anteriorly. Forewings pale ochreous, partially shaded with umber-brown, especially below the fold, on the outer half of the costa, and around the apex where the dark scales project more or less through the pale ochreous cilia; the extreme base of the costa is narrowly black, a few black scales being scattered along the base of the dorsum; at one-third from the base are two small black spots placed obliquely in the cell, sometimes confluent, and beneath the outer one is a stronger black spot in the fold; beyond these, at the end of the cell and preceded by a small elongate spot at its upper edge, is an oblique reniform patch, covering the discoidal and produced inward from the upper angle —these markings are subject to more or less modification, and are less distinct in some specimens than in others, but their position is uniformly maintained. Exp. al. 13-14 mm. Hindwings pale straw-whitish; cilia pale ochreous. Abdomen and Legs pale ochreous, the tibiae and tarsi slightly shaded with brownish on their outer sides.

Type \eth (98242); \Diamond (98241) Mus. Wlsm.

Hab. TENERIFE: Forest de la Mina, 7. IV. 1904 (Eaton); Realejo, 7. V. 1907 (Wlsm.); Las Mercedes, 19. V. 1907 (Wlsm.); La Laguna, 23. V. 1907 (Wlsm.); Tacaronte, 31. V. 1907 (Wlsm.).

Thirteen specimens.

This species is somewhat larger on the average than Apatema fusciatum, and the forewings are uniformly broader; their invariably ochraceous ground-colour and the distribution of the black spots, with the absence of any distinct shade across the base, serve to distinguish it from its ally—like the forewings the hindwings are also of an entirely different hue. It does not appear to be a common species.

23. (349°2) AMBLOMA, gn. n.

 $(\ddot{a}\mu\beta\lambda\omega\mu\alpha = abortion.)$

Type Ambloma brachyptera Wlsm.

Antennae without pecten; a little longer than the forewings; simple in \mathcal{C} . Maxillary Palpi short. Labial Palpi bent upwards, reaching to vertex; median joint moderately clothed with slightly projecting scales below at apex; terminal joint short, smooth. Head and Thorax smooth. Forewings very short, tapering rapidly to a slightly depressed, obtusely pointed apex; costa evenly convex, flexus rather squarely developed, dorsum straight beyond the flexus: neuration 12 veins; 7 and 8 stalked, to costa; 6 out of stalk of (7+8); cell short. Hindwings $\frac{2}{3}$, much shorter, but of the same shape as the forewings; cilia $1\frac{1}{2}$: neuration 8 veins; 6 and 7 stalked; 3 and 4 stalked. Abdomen smooth. Legs, hind tibiae moderately hairy.

Allied to Apatema Wlsm. and Symmoca Hb., but differing in

its curiously aborted appearance, which recalls the form of Embryonopsis Etn. and Hodegia Wlsm., both insular forms, and, in the European fauna, the $\, \, \, \, \, \, \,$ of Chimabacche Hb.

47. (3050·3) Ambloma Brachyptera, sp. n. (Plate LI. fig. 18.)

Antennae dark greyish fuscous, the basal joint hoary white. Palpi greyish fuscous externally, hoary white on their inner sides, and around the apex of the median joint. Head and Thorax hoary white, the latter with grey sprinkling. Forexings hoary white, profusely sprinkled with dark stone-grey scales, but devoid of pattern; a slight spot of ochreous suffusion on the cell a little before the middle of the wing; cilia hoary whitish, with a slight admixture of grey, especially about the tornus. Exp. al. 9 mm. Hindwings whitish grey; cilia pale grey. Abdomen ochreous: anal tuft hoary white. Legs whitish, dusted with brownish grey, the tarsi faintly banded.

Type ♂ (99007) Mus. Wlsm.

Hab. TENERIFE: Guimar, 6. III. 1907. Unique.

Found under leaves of *Lotus sessilifolius*, on the black sand of the coast near Puerto Guimar. No other specimen seen.

24. (348'01) CHERSOGENES, $gn.\ n.$

 $(\chi \epsilon \rho \sigma \sigma \gamma \epsilon \nu \dot{\eta} s = \text{bred on dry land.})$

Type Chersogenes victimella Wlsm.

Antennae 1, simple in \circlearrowleft ; without pecten. Maxillary Palpi moderate. Labial Palpi extending fully three times the length of the head beyond it; median joint thickly clothed above and beneath, the lower scales projecting nearly half the length of the slender, erect terminal joint, beyond its base. Haustellum moderate. Head and Thorax moderately smooth. Forewings narrow, elongate, lanceolate, with straightened costa and slightly curved dorsum tapering to a point: neuration 12 veins; 7 and 8 stalked, 7 to termen; rest separate. Hindwings as broad as the forewings, considerably shorter, but much the same shape; cilia $1\frac{1}{2}$: neuration 8 veins; 6 and 7 long-stalked; 3 and 4 long-stalked. Abdomen smooth, somewhat flattened; uncus and claspers strongly developed. Legs, hind tibiae slightly hairy.

This genus is most nearly allied to Epanastasis Wlsm., but

differs in the structure of the palpi.

48. (3022·01) CHERSOGENES VICTIMELLA, sp. n. (Plate LI. fig. 17.)

Antennae dark brownish fuscous. Palpi hoary whitish, sprinkled with fuscous scales on their outer sides. Head and Thorax cinereous, dusted with fuscous. Forewings pale cinereous,

densely sprinkled with fuscous throughout, except along a narrow line running from the base to the lower angle of the cell, with a slight break about its middle; on either side of this break is a small spot of raised dark fuscous scales, two similar spots appearing on either side of the outer end of the pale line, the lower spot in each case being a little further from the base than the one above it; there is also an indication of a small group of dark fuscous scales resting on the upper edge of the cell at its base; cilia cinereous, sprinkled with fuscous. Exp. al. 12 mm. Hindwings and cilia dark tawny brown. Abdomen brownish cinereous. Legs pale cinereous, slightly dusted with fuscous. Type 3 (99008) Mus. Wlsm.

Hab. Tenerife: Santa Cruz, 29. IV. 1907. Unique.

The most persistent efforts to secure another specimen of this very distinct species were unsuccessful.

25. (348'02) EPANASTASIS, gn. n.

 $(\epsilon \pi a \nu \dot{a} \sigma \tau a \sigma i s = \text{rebellion.})$

Type Holcopogon sophroniellus Rbl.

Antennae nearly as long as the forewings, slightly serrate; without pecten. Maxillary Palpi short, dependent. Palpi clothed with projecting scales beneath, these extending beyond the base of the terminal joint; terminal joint not more than half the length of median, smooth. Haustellum welldeveloped. Head and Thorax smooth. Forewings elongate, lanceolate, the dorsum slightly more convex than the costa: nouration 12 veins; 7 and 8 stalked, 7 to termen; rest separate. Hindwings 1, apex slightly depressed, termen very oblique, almost sinuate, flexus moderately developed; cilia 1: neuration 8 veins; 6 and 7 long-stalked: 3 and 4 stalked. Abdomen smooth. Legs, hind tibiae slightly hairy above.

Has much the appearance of Apiletria Ldr., to which it is closely allied, but differs in having vein 7 of the forewings to termen, in which it agrees with Symmoca Hb.; differing from Symmoca, as also from Apiletria, in its more roughly clothed palpi, with much

shorter terminal joint.

49. (3022.02) Epanastasis sophroniella Rbl.

Holcopogon sophroniellus Rbl. Ann. KK. Hofmus. IX. 18, 89–90 no. 174 (1894) : XI. 128-9, 147 no. 196, Pl. 3 · 10-10^a (1896) : XIII. 381 no. 210 (1899)³: XXI. 44 no. 217 (1906)⁴: Stgr-Rbl. Cat. Lp. Pal. II. 160 no. 2980 (1901) 5.

Type ♂ (61057) Mus. Wlsm.

Hab. Canaries 1-5 — TENERIFE 1-5: IV. 1885 (Leech) 1—GRAN Canaria 2-3: Teror, 10. V. 1895 (*Hedemann*) 2.

Despite persistent search I did not meet with this species.

26. (348) SYMMOCA Hb.

50. (3035·1) Symmoca canariensis Rbl. (Plate LII, fig. 1.)

Symmoca canariensis Rbl. Ann. KK. Hofmus. XXI. 38-9, 44 no. 218 (1906) ¹.

Hab. TENERIFE¹: 1905 (W. W. White)¹: Santa Cruz, 4-29. II. 1907 (Wlsm.), 3. IV. 1904 (Eaton), 29. IV. 1907 (Wlsm.); Guimar, 2. III - 14. IV. 1907 (Wlsm.); Arafo, 13-14. IV. 1907 (Wlsm.); Puerto Orotava, 21. IV - 10. V. 1907 (Wlsm.); La Laguna, 23. V.

1907 (Wlsm.).

I carefully examined the single specimen, in Mr. White's collection, at Guimar, which is the type of Symmoca canariensis Rbl., and bearing in mind the appearance of Holcopogon sophroniellus Rbl., at first imagined they must be the same, but, although I cannot agree with Prof. Rebel in placing sophroniellus in the genus Holcopogon Stgr. (which has been wrongly included in the Gelechiadae, and must be removed to the Hyponomeutidae), the shorter terminal joint of the palpi, even without other more important characters, is at once sufficient to separate it from the Symmoca. I found S. canariensis almost the commonest insect in the Island; it was abundant at Santa Cruz and Guimar, but I have no clue to the habits of the larva.

A fine series of 64 specimens exhibits considerable variation: in some the costal margin is broadly and conspicuously darkened, in contrast to the dull white ground-colour; in others a suffusion extends more or less over the whole wing; while in others again there is a yellowish streak along the cell, or sometimes two pairs of obliquely placed fuscous spots, before and beyond the middle, recalling vividly the pattern of oxybiella Mill., but more obliquely placed than in that species, and exhibiting scarcely any of the yellowish scales which are there to be found on the outer edge of the spots. Some of the smaller and more suffused varieties show a faint indication of these spots and approach very closely, except in colour, the only two specimens which I am obliged to eliminate from my series and to describe under another rame (aegrella, sp.n.). S. canariensis was not found at the time and place where the new species occurred.

51. (3035·2) Symmoca Aegrella, sp. n. (Plate LII. fig. 2.)

Antennae and Palpi sandy ochraceous. Head and Thorax pale ochreous. Forewings sandy ochreous, dusted with fawn-brownish scales, slightly more thickly above and below than upon the cell; cilia pale sandy ochreous. Exp. al. 13-14 mm. Hindwings shining, pale straw-ochreous, a little more brownish toward the apex; cilia very pale sandy ochreous. Abdomen and Legs pale sandy ochreous.

Type 3 (99009) Mus. Wlsm.

Hab. Tenerife: La Laguna, 9. VI. 1907. Two specimens. This species, which agrees with canariensis in having veins 3

and 4 of the forewings short-stalked, differs in its ochrous, rather than whitish, or greyish, colouring; in its paler and more ochreous hindwings, and in the absence of a dark shade along the outer side of the median joint of the palpi, which are also somewhat more slender in appearance.

27. (347) EPIDOLA Stgr.

52. (3019) EPIDOLA STIGMA Stgr.

Epidola stigma Stgr. Stett. Ent. Ztg. XX. 244 no. 93 (1859)¹; Stn. Tin. S-Eur. 141, 152 no. 32 (1869)²; Stgr-Rbl. Cat. Lp. Pal. II. 162 no. 3019 (1901)³.

Hab. S. EUROPE—Corsica: Punta Parata,

Frankenia pulverulenta, 7. VI, excl. 1. IX. 1899 (Wlsm.); Ajaccio, \oplus Crithmum maritimum, 10. VI, excl. 7. IX. 1899 (Wlsm.)—S. Spain ¹⁻³: Chiclana, ⊕ Quercus coccifera, IV, excl. VI (Stgr.) ¹⁻²; Coto, Granada, \bigoplus Cistus, Helianthemum, IV-V. 1901 (Wlsm.). N. AFRICA—Morocco: Tangier, \oplus 29. II. 1902 (Wlsm.); Cape Spartel, \oplus on palings, 14. IV. 1902 (Wlsm.)—Algeria: Constantine (Stor.). Canaries—Tenerife: Santa Cruz, \oplus on rocks. 30. I = 10. V. 1907 (Wlsm.).

I found, at different dates, six cases of this species on the rocks, above the Hotel Quisisana at Santa Cruz, but failed to rear any of them, repeating my previous experience as to the difficulty of breeding it. From more than a hundred cases, collected at Granada, not a single specimen emerged; but the few cases previously found in Corsica all produced the moth in due course. I am quite at a loss to account for the failures. Similar cases are made by species of the Australian genus Ocystola Meyr. (Oecophoridae).

II. BLASTOBASIDAE.

28. (351) BLASTOBASIS Z.

Prof. Rebel recorded the occurrence of Blastobasis roscidella Z. in the Canaries [Ann. KK. Hofmus. IX. 18, 90 no. 177 (1894)], on the strength of a specimen (61060) received from me in 1893. This was one of a series of seven specimens (61058-64) taken in Tenerife, by the late Mr. J. H. Leech, in April 1885, and is now recognised as Scythris fasciatella Rgt. (3536), vide no. 86, p. 973.

Five σ σ from La Laguna at the end of May and the beginning of June: one of these specimens (σ 98233), with broader and more pointed wings, taken on May 23rd, is abnormally large (exp. al. 19.5 mm.) for a representative of this species, but it cannot

otherwise be separated.

Rebel mentions a single worn δ , with notched antennae and hindwings similar to those of *phycidella Z.*, as taken at Orotava, 20. IV [*Blastobasis sp.* Rbl. Ann. KK. Hofmus. XI. 132 no. 201^b (1896)]. He apparently regarded it as distinct from both *phycidella* and *rubiginosella*.

54. (3056) Blastobasis Rubiginosella Rbl.

= sp. 179 Rbl.

Blastobasis sp. Rbl. Ann. KK. Hofmus, IX. 18, 91 no. 179 (1894)¹: XXI. 44 no. 223 (1906)². Blastobasis rubiginosella Rbl. Ann. KK. Hofmus. XI. 130–1, 147 no. 200, Pl. 3 ¹ 12 (1896)³: XXI. 44 no. 221 (1906)¹: Stgr-Rbl. Cat. Lp. Pal. II. 163 no. 3056 (1901)⁵.

Hab. TENERIFE ¹⁻³: IV. 1885 (Leech) ¹; Guimar, 4. III – 16. IV. 1907 (Wlsm.); La Laguna, 8. IV. 1904 (Eaton), 7. VI. 1907 (Wlsm.); Puerto Orotava, 21. IV. 1895 (Hedemann) ³, 30. IV. 1907 (Wlsm.); Las Mercedes, 29. V – 7. VI. 1907 (Wlsm.); Tacaronte, 31. V. 1907 (Wlsm.).

Twenty-eight specimens were taken at Guimar, Tacaronte, Puerto Orotava, Las Mercedes, and La Laguna, from March 4th

to June 7th, but the larva remains unknown.

The specimen mentioned by Rebel as *Blastobasis sp.* 179 (*l. c.* 1) is in my collection (\circlearrowleft 61053); it is undoubtedly a worn \circlearrowleft of *rubi-ginosella*; the type of the species, when subsequently described, having been a Q.

55. (3056·1) Blastobasis velutina, sp. n. (Plate LII. fig. 4.)

Antennae and Palpi ash-grey, the latter sprinkled with black scales. Head and Thorax ash-grey. Forewings ash-grey, with a short square patch of black scales at the base of the costa, followed at a distance equal to its own length by a broad transverse band of black scales, some conspicuously raised, especially along its outer edge, which is convex and reaches nearly to the middle of the wing; its inner edge approaches nearer to the base on the dorsum than on the costa; beyond this patch, which in some specimens appears divided into two fasciae, the wing is much more sparingly bestrewn with black scales, which however are somewhat thickened on the margins at three-fourths, and around the apex; cilia brownish cinereous. Exp. al. 11-14 mm. Hindwings brownish grey; cilia brownish cinereous. Abdomen ash-grey, shaded at the sides and posteriorly with black; pale cinereous beneath. Legs brownish cinereous, the tarsi blackish, with whitish cinereous annulations.

Type 3 (98258); 9 (98263) Mus. Wlsm.

Hab. Tenerife: Guimar, 9-30. III. 1907; Tacaronte, 31. V.

1907; La Laguna, 9. VI. 1907. Four specimens.

Allied to rubiginosella Rbl., but distinguished by the broad, dark, transverse band before the middle of the wing. The antennae are deeply notched in the β .

56. (3060) Blastobasis fuscomaculella Rgt.

= seeboldiella Kreithn.⁴; = *marmarosella Rbl. (nec Wlstn.) ³⁻⁴. Oecophora fuscomaculella Rgt. Bull. Soc. Ent. Fr. XLVIII. (5 s. IX: 1879). p. cxli (1880) ¹. Oecophora seeboldiella Kreithner Verh. Hab. Spain $^{2-5, 7, 10}$: Bilbao $^{2-4, 7}$, V 7 , VII 2 , VIII 7 — Portugal $^{1, -5, -10}$: Coimbra 1 . Madeiras — Madeiras $^{5, -10}$. Canaries $^{3-6, -8-10}$ —Tenerife $^{3-4, -6, -8-9}$: IV. 1885 (*Leech*) 4 ; La Laguna, 23. V − 7. VI. 1907 (*Wlsm.*), VI. (*Cabrera*) 4 ; Puerto Orotava, IX. 1889 (*Simony*) $^{3, -8}$ — Hierro 8 : Valverde, 9–14. II. 1898 (*Hintz*) 8 .

This is apparently a scarce species, I only met with three specimens. Valverde is in Hierro, not in Tenerife.

29. (351·1) PROSTHESIS, gn. n. (πρόσθεσις=an addition.)

Type Prosthesis exclusa, sp. n.

Antennae with peeten; σ simple, or minutely ciliate, not notched, nor attenuate at the base. Maxillary Palpi short, converging. Labial Palpi recurved, reaching above the vertex, closely clothed; terminal joint shorter than median. Haustellum scaled at the base. Head and Thorax smooth. Forewings narrow, elongate, evenly lanceolate: neuration 12 veins; 7 and 8 stalked, to costa. Hindwings nearly as broad as the forewings, acutely lanceolate, the costa straighter than the dorsum: neuration 7 veins (3 and 4 coincident); (3+4) and 5 stalked; 6 and 7 remote, almost parallel. Abdomen smooth. Legs, hind tibiae moderately hairy.

This genus agrees with Blastobasis Z., Epistetus Wlsm., and Zenodochium Wlsm. in having 3 and 4 of the hindwings coincident, stalked, or connate, with 5. It differs from Epistetus and Zenodochium in having a pecten instead of a conchoidal shield of scales on the basal joint of the antennae, and from Blastobasis, with which it agrees in having a pecten on the basal joint, in the absence of a notch.

57. (3067·1) Prosthesis exclusa, sp. n. (Plate LII. fig. 5.)

Antennae stone-whitish. Palpi stone-greyish, sprinkled with fuscous; the median joint fuscous on its outer side nearly to the apex. Head and Thorax stone-grey. Forewings pale stone-grey. sparsely sprinkled with fuscous and rust-brown scales; a small spot at the base of the costa, a narrow fascia at one-third from the base, much mixed with rust-brown and strongly angulated outward on the cell, whence it runs nearer to the base on the dorsum than on the costa; at two-thirds a rather strong group of fuscous and brownish scales, on the dorsum. is more or less connected by scattered scales across the wing to a smaller costal spot a little nearer to the apex, and these again are more or less connected with each other by a chain of six or seven obscure marginal spots running around the apex; cilia pale brownish grey. Exp. al. 12-14 mm. Hindwings grey; cilia brownish grey. Abdomen greyish fuscous, with narrow, shining, pale steely grey, transverse bands. Legs stone-greyish. thickly speckled with brownish fuscous on their outer sides.

Type 3 (98291); 9 (98298) Mus. Wlsm.

Hab. Tenerife: Puerto Orotava, 25. IV – 3. V. 1907; La Laguna, 23. V – 9. VI. 1907; Las Mercedes, 29. V – 7. VI. 1907. Nineteen specimens.

30. (352·1) ZENODOCHIUM Wlsm. ZENODOCHIUM Wlsm. Ent. Mo. Mag. XLIV. 49 (1908). Type Zenodochium monopetali Wlsm.

58. (3069·2) Zenodochium polyphagum, sp. n. (Plate LII. fig. 6.)

= Blastobasis sp. Rbl. Ann. KK. Hofmus. XI. 131, 147 no. 201a (1896) 1: XXI. 44 no. 222 (1906) 2.

Antennae brownish fuscous. Palpi brownish fuscous, the distal end of the median joint narrowly whitish. Head and Thorax whitish, sprinkled, or sometimes entirely suffused, with brownish fuscous. Forewings usually dirty whitish, but varying from clear white to dull ash-colour, with brownish fuscous streaks and blotches; the usually paler basal third of the wing has a small spot at the base of the costa, one or two short length-streaks on and above the fold, and another near the dorsum, and is sometimes also profusely sprinkled with brownish fuscous scales; at onethird occurs a slightly inverted triangular costal spot, between which and an ill-defined, outwardly oblique, dorsal patch the paler ground-colour asserts itself in a narrow, oblique, separating band; on the median area is a short length-streak along the upper edge of the cell, and much sprinkling (sometimes considerable suffusion) of brownish fuscous; at three-fourths is a transverse, narrow, brownish fuscous band, slightly inverted from costa to dorsum, and sometimes interrupted below the costa, and beyond is another short median length-streak and a series of about six dentate streaks around the margin; cilia hoary, faintly sprinkled and narrowly striated with brownish grey. Exp. al. 13-20 mm. Hindwings brownish grey; cilia shining, yellowish brown along their base, greyer beyond. Abdomen grey. Legs brownish grey. Type 3 (98227); 9 (98221); PT. var. 3 (98210) Mus. Wlsm.

Hab. Tenerife ¹⁻²: Puerto Orotava, 24. IV. 1895 (Hedemann) ¹, 23. IV − 7. V. 1907, \oplus in refuse on Artemisia canariensis, 27. III, excl. 4. VI − 2. VIII. 07, \oplus Allagopappus dichotomus, 4. IV, excl. 4. V − 4. VII. 07, \oplus Senecio kleinia, IVe, excl. 13–31. V. 07, \oplus Sonchus gummifer, 23. IV, excl. 23. VI. 07, \oplus Pinus canariensis, 20. IV, excl. 19. V − 11. VI. 07, \oplus Rubia fruticosa, II, excl. 18. V. 07, \oplus Cytisus proliferus, 22. IV, excl. 29. IV − 10. VI. 07, \oplus Rhus coriaria, 28. IV, excl. 6. VI. 07 (Wlsm.); Bajomar, 26. V. 1907 (Wlsm.). Thirty-six specimens (33 bred, 3 captured).

The species varies much in the amount of sprinkling, or suffusion, of brownish fuscous on the ashy ground-colour, some of the whiter varieties being more plainly marked than others, but all possess the oblique pale separating line between the costal triangle and dorsal blotch. In appearance it reminds one rather of Tecmerium anthophagum Stgr., but its nearest ally is Zenodochium xylophagum Wlsm., a much darker species with indistinct

markings. I bred thirty-six specimens from accumulated refuse on Artemisia canariensis (3), Allagopappus dichotomus (13), Senecio kleinia (4), and Sonchus gummifer (1)—Compositae; Pinus canariensis (6)—Coniferae; Rubia fruticosa (1)—Rubiaceae; Cytisus proliferus (4)—Leguminosae; and Rhus coriaria (1)—Terebinthaceae; these are, I believe, all plants indigenous to the Island. The larva frequently bores into the stem of the foodplant before pupation, leaving a hole from which the imago escapes.

III. OECOPHORIDAE.

31. (369'01) AGONOPTERYX Hb.

Forewings: 2 and 3 stalked; 7 and 8 stalked.

Type Pyralis ocellana F.

=†AGONOPTERIX Hb. (Type ocellana F.); =PINARIS Hb. (Type arenella S-D.); =TICHONIA Hb. (Type atomella S-D.); =EPELEUSTIA Hb. (Type liturella Hb.); =HAEMYLIS Tr. (Type assimilella Tr.); =*VOLUCRA Z. (conterminella Z.), nec Ltr.; = DEPRESSARIA (A) Meyr.

Wallengren [Entomologisk Tidskrift II. 81 (1881)] described the new genus Siganorosis for species agreeing with heracliana DG. in having veins 2 and 3 of the forewings separate, thus restricting the use of Depressaria Hw. to species with 2 and 3 stalked. Unfortunately he overlooked the fact that in 1828 Curtis had cited heracleana as the type of Depressaria Hw., and figured its neuration. Siganorosis Wlgrn. must therefore sink as a synonym of Depressaria Hw., and also of Volucra Ltr. The species having 2 and 3 of the forewings stalked form a natural and easily recognisable genus and should be known as Agonopteryx Hb.

59. (3193·1) Agonopteryx cinerariae, sp. n. (Plate LII. fig. 7.)

Antennae ochraceous, much clouded beyond the base with smoky fuscous. Palpi pale ochreous, the terminal joint minutely tipped with black, and having a black band around it above the middle. Head and tufted Thorax pale ochreous. Forewings with the costa moderately convex, apex depressed, termen oblique; pale ochreous, with a few darker fawn-ochreous shades tending to define the neuration; more or less profusely sprinkled with scattered black dots, some being placed along the termen, some on the costa, one on the costa beyond the middle, in position to form an equilateral triangle with two others on the disc, above and near the first of which is sometimes a blackish patch; a small black marginal spot also lies near the base of the dorsum. Exp. al. 17–20 mm. Hindwings very pale, shining, whitish ochreous; cilia still paler. Abdomen and Legs pale straw-ochreous.

Type & (99011); PT. var. & (99012) Mus. Wlsm.

Hab. Tenerife: Arafo, 13. IV. 1907 (Wlsm.); Barranco Lorez, near Orotava, ⊕ Senecio (Cineraria) populifolius, 7. V, excl. 11-

20. VI. 1907 (17sm.). Seven specimens.

Larvae found in April and May, at Guimar and near Orotava, on Senecio (Cineraria) populifolius and heritieri, mining between the upper and under surfaces of the leaves, causing a slightly puckered appearance, but very difficult to detect owing to their pale greenish white colour. Six specimens bred in June, and a single 3 taken on the wing above Arafo, April 13th.

Allied to assimilella Tr., but easily separated by the distinct black spotting on the under side of the costa of the forewings, which are, as are also the hindwings, much paler than in that species.

60. (3201.1) AGONOPTERYX CONCILIATELLA Rbl.

Depressaria conciliatella Rbl. Ann. KK. Hofmus. VII. 272–4, 283 no. 55. Pl. 17 \cdot 14 \circ (1892) \cdot ; Wlsm. Tr. Ent. Soc. Lond. 1894. 538, 546 no. 40 (1894) \cdot ; Stgr-Rbl. Cat. Lp. Pal. II. 171 no. 3223 (1901) \cdot : Rbl. Ann. KK. Hofmus. XXI. 44 no. 226 (1906) \cdot .

Hab. Sicily ¹⁻³: Palermo ¹. Madeiras ²⁻³—Madeira ²: Funchal; The Mount (Wollaston) ². Canaries ¹⁻⁴—Tenerife ¹: Agua Mansa and Pedro Gil, ⊕Cytisus proliferus, 20. IV, excl. 20–23. V. 1907 (Wlsm.); Pedro Gil, 1420 m., 30. VII. 1889 (Simony) ¹—Gran Canaria ¹: San Mateo, 805 m., 7. VIII. 1890 (Simony) ¹.

The only named species, of the unrestricted genus Depressaria, recorded by Rebel in his complete list (1906) is conciliatella. In 1894 (l. c. 2), I wrote that if I had rightly identified this species it was very variable. I have now two specimens, bred from larvae feeding in the leading shoots of Cytisus proliferus, from Pedro Gil and Agua Mansa respectively, which are much darker than the Madeiran examples, but not distinguishable in the position and character of the markings. Professor Rebel, throughout his description, compares conciliatella with "yeatiana F.," but it is much more nearly allied to scopariella Hnm., from which indeed some of the less speckled varieties are almost indistinguishable. The easiest way to separate them is by the costal markings on the underside: in conciliatella there is a wide pale band around costa and termen, much peppered and streaked with fuscous along the basal half of the costa: in scopariella the pale band is narrower and decidely less speckled.

61. (3222) Agonopteryx yeatsana F.

=†yeatiana F., ‡ yeatsana. (T. P. Yeats, nom. pr.) Puralis yeatiana F. Sp. Ins. II. 286 no. 60 (1781)¹. Depressaria yeatiana Rbl. Ann. KK. Hofmus. VII. 272-4 (1892)²; Stgr-Rbl. Cat. Lp. Pal. II. 171 no. 3222 (1901)³.

Hab. C-S. EUROPE 1-3 — Corsica: Corté, ⊕ Heloscyadium

sp., 7. VI, excl. 20. VI. 1898 (Wlsm.)—S. France: R. Var, ⊕ Peucedanum palustre, 10. IV, excl. 18. VI. 1896 (Wlsm.). N. AFRICA—Morocco: Tangier, ⊕ Heracleum sp. ?, 24 IV, excl. 19. V. 1902 (Wlsm.). Canaries — Tenerife: Puerto Orotava, 4. V. 1907, ⊕ Umbellifer, 9. V, excl. 10. VI. 1907 (Wlsm.).

Six specimens taken, and one bred from an Umbellifer, growing under dripping rocks on the sea-coast, near Orotava. The plant appeared to be the same as that from which I bred this species in Corsica, in 1898, and which was named for me at the time "Heloscyadium sp.", but I am not sure that the species occurs in Tenerife: in any case my botanical knowledge is quite inadequate to decide the point from such specimens as were available at the date on which the larva was found near Orotava. My experience is, that this species occurs only on marshy ground; I have also bred it from Peucedanum palustre, gathered at the mouth of the Var, on the Riviera, and from Herueleum sp., at Tangier.

62. (3232·1) AGONOPTERYX PEREZI, sp. n. (Plate LII. fig. 8.) =*applana Wlsm. (nec F.).

Depressaria applana Wlsm. Tr. Ent. Soc. Lond. **1894**. 538, 546 no. 41 (1894) ¹.

Antennae smoky fuscous. Palpi cinereous, the median joint thickly sprinkled with black and tawny on the outer side, except in a narrow band around its upper end; terminal joint with a narrow black band around its base, a broader one before its apex, and the extreme apex minutely black. Head and Thorax cinereous, more or less tinged with fuscous; the latter with an elevated crest posteriorly. Forewings tawny reddish fuscous, with smoky black suffusion and speckling; a pale ochreous patch at the extreme base, its outer edge straight and black-margined to the upper edge of the cell, above which it is angulated and produced outward along the costa, and gradually absorbed in the darker groundcolour; on the cell, at one-third, are two clearly defined, almost contiguous, but obliquely diverging, black spots, the lower one slightly beyond the upper—both followed by a few ochreous scales, produced and broken into two spots, in line with the lower one on the cell; the slightly paler costa is obscurely spotted with dark fuscous throughout, and the termen is also narrowly spotted, the fuscous shading on the wing tending to follow and indicate the neuration; cilia corresponding in colour to the wing-surface; underside shining, sericeous, the costa and termen strongly speckled with fuscous. Exp. al. 16-20 mm. Hindwings and cilia shining, pale cinereous, the cilia with slender parallel shade-lines running through them; underside shining, sericeous, the costa and termen strongly speckled with fuscous. Abdomen and Legs pale cinereous, the tarsi with four fuscous bands.

Type ♂ (99018); ♀ (99019) Mus. Wlsm.

Hab. Madeiras ¹—Madeira ¹. Canaries—Tenerife: Puerto Orotava, ⊕ Ruta pinnata, 14. V, excl. 4. VI - 1. VII. 1907

(Wlsm.). Twenty-four specimens.

The pale green larva rolls the leaves of *Ruta pinnata*, an indigenous and somewhat local plant, to which my attention was specially called by my friend Dr. George Perez, after whom I have named this *Agonopteryx*, and whose great assistance in the botanical work connected with my study of the Tenerife Lepidoptera I gratefully acknowledge.

As compared with Agonopteryx applana F., the chief points of difference noticeable in perezi are that the pale basal patch is sharply angulate (not curved outward) at the radius, along and above which are some distinctly ochreous scales; the discal spots are yellowish, not white, and the antennae are shorter. Looking again at the rather poor specimen which I recorded from Madeira, as applana, in 1894, I am now inclined to regard this as perezi.

32. (369) DEPRESSARIA Hw.

Forewings: 2 and 3 separate; 7 and 8 stalked.

Type Phalaena Tortrix heracleana (L.) DG., F., Hw.

Depressaria Hw. (Type heracleana Hw.); = Pyralis F. (II.) Ltr.; [=Piesta Blbg. (Type heracleana L.) LN.]; = \downarrow " Pyrale, Volucre" Ltr. (Type heracleana F.); = Volucra Ltr. (Type heracleana F.); = Siganorosis Wlgrn. (Type heracleana L., Wlgrn.); = Depressaria (B) Meyr.

63. (3299·1) Depressaria tenerifae, sp. n. (Plate LII. fig. 9.) = Depressaria sp. Rbl. Ann. KK. Hofmus. XXI. 39, 44 no. 227 (1906) 1.

Antennae smoky fuscous. Palpi cinereous, densely speckled with smoky fuscous externally, and with a fuscous ring above the middle of the terminal joint. Head and Thorax pale slaty greyish, more or less sprinkled with tawny fuscous. Forewings slaty greyish, suffused, and obscurely blotched, with smoky fuscous; a very dark patch at the base, below the fold, leaving a narrow pale margin within it, is diluted upward and outward, and followed by two clouds of a similar colour on the cell, one before and one-beyond the middle, of which the first is the darker, owing to black scaling continued from its lower edge in a series of two or three small spots reaching to the end of the cell; beyond the cell is a strong, outwardly curved, dark fuscous shade, preceding the speckled margin and cilia, the latter are delicately rosy-tipped. Exp. al. 17–19 mm. Hindwings and cilia pale, shining, rosy cinereous. Abdomen and Legs shining, cinereous; the tarsi with four fuscous bands.

Type $\c (99020)$; $\c (99021)$; $\c (99022)$ Mus. Wlsm. Hab. Tenerife: 1905 (White) ; Santa Cruz, $\c Artemisia$ canariensis, 11. II, excl. 19. III − 3. IV. 1907 (Wlsm.); Guimar, ⊕ Artemisia canariensis, 25. III, excl. 9. IV − 23. V. 1907 (Wlsm.).

Sixteen specimens.

Bred from a rather stout green larva, feeding in the leading shoots of Artemisia canariensis, at Santa Cruz and Guimar. As compared with the European species which feed on Artemisia, it is distinctly more suffused in its colouring, the darker patches being unaccompanied by any lines of whitish scales; indeed the whole insect has a much more silky, smooth appearance, with some gloss, not only in the hindwings, but also on the anterior pair. It is perhaps nearest to absinthivora Frey, but the absence of any outward elongation of the median shade is a good character by which it may readily be distinguished.

64. (3306) Depressaria apiella Hb.

=nervosa Hw.; =*heracliana Wlsm. (nec DG.).

Hab. EUROPE ^{1-s}. N. AFRICA—Morocco: Tangier, ⊕ Ferula sp., excl. 19. V. 1902 (Wlsm.); ⊕ Oenanthe peucedanifolia, 6. V, excl. 7-15. VI. 1902 (Wlsm.); ⊕ Thapsia garganica, 9. V, excl. 7. VI. 1902 (Wlsm.). Madeiras ⁵—Madeira: (Wollaston) ⁵. Canaries—Tenerife: Guimar, ⊕ Bupleurum aciphyllum, 6. III, excl. 16. IV. 1907 (Wlsm.); ⊕ Umbellifer, 14. IV, excl. 22. V. 1907 (Wlsm.). UNITED STATES ^{4,7-8}—Oregon ^{4,7-8}: Grant co.: Camp Watson, IV^m. 1872 (Wlsm.): Jackson co.: near Rogue River, 4-6. V. 1872 (Wlsm.).

For more than half a century apiella Hb. (1796) has been sunk as a synonym of nervosa Hw. (1811): so long as these two names are held to pertain to the same species, it is obvious that that

species must be named apiella Hb.

Two specimens bred from an *Umbellifer*, found at Guimar, and one from the rare *Bupleurum aciphyllum* (=salicifolium) appear to be inseparable from this species: they agree exactly with specimens bred in Morocco, in 1902, from *Ferula*, *Oenanthe peucedanifolia*, and *Thapsia garganica*, and are only distinguished from my European series by their slightly larger size and darker colour, partly due to the freshness of the specimens. This species has not been met with in the United States since 1872, when I took two specimens in Oregon. I again refer to these two specimens to give the exact localities, viz., (91970) Camp Watson,

Grant Co., in Northern Oregon, taken in April 1872, and (91971) taken in Jackson Co., in Southern Oregon, 4–6 June 1872, when near Rogue River. These two American specimens have vein 5 of the hindwings out of the stalk of 3 and 4, in which they agree with Canary, Tangier, Madeira, and European specimens which have 5 connate with, or out of the stalk of 3 and 4; a character which occurs also in discipunctella HS. (=*pastinacella Stn.). The specimen recorded by me from Madeira in 1894 (l. c. 5) as "Siganorosis heracliana DG." is a bleached example of apiella Hb.

Coleophora orotavensis Rbl. Ann. KK. Hofmus. XI. 137–8, 147 no. 214, Pl. 3 · 16 ♀ (1896) ¹ : XXI. 44 no. 234 (1906) ² : Stgr-Rbl. Cat. Lp. Pal. II. 193 no. 3713 ((1901) ³.

Hab. Tenerife ¹⁻³: Santa Cruz, 26. XII – 26. I. 1907 (Wlsm.); Guimar, 28. II – 12. IV. 1907 (Wlsm.), 24. III. 1904 (Eaton); Tacaronte, 1. IV. 1902 (Eaton); Puerto Orotava, 21–30. IV. 1905 (Hedemann)¹, 21. IV. 1907 (Wlsm.).

Exceedingly common everywhere. It seems to be attached to *Chenopodium*, and to appear in successive broods almost continuously.

67. (3713·1) Coleophora Micromeriae, sp. n.

Antennae white, annulate with greyish fuscous; the basal joint roughly clothed, but not tufted. Palpi white, a broad greyish fuscous band spreading around the apex of the median, and base of the terminal joint, including some slightly projecting scales from the former. Head white, slightly shaded along the middle with grevish fuscous. Thorax white above; tegulae touched with greyish fuscous. Forewings greyish fuscous, the costa narrowly pure white from the base, widening outward, and continued to the apex, before which the costal cilia are slightly touched with grey; there is a less conspicuous line of white scaling along the fold and slightly diffused downward across the space beneath it to the dorsum, the base of the terminal cilia being also white, forming a streak which runs out through those of the apex; with this exception the cilia are pale brownish grey; the marginal white lines are clearly visible on the underside. Exp. al. 8-11 mm. Hindwings very pale bluish grey; cilia pale brownish grey, becoming whitish at their tips around the apex. Abdomen brownish grey above, white beneath; anal clothing whitish. Legs white, the hind tarsi faintly speckled.

Hab. Tenerife: Puerto Orotava, 19. II. 1907, 5.V. 1907 (Wlsm.); Guimar, 27. II − 14. IV. 1907 (Wlsm.), ⊕ Micromeria varia, 23. II, excl. 10. V. 1907 (Wlsm.); Cruz de Afur, 5. IV. 1904 (Eaton); Forest de la Mina, 7. IV. 1904 (Eaton). Sixteen specimens, one bred.

The case is brown, short and cylindrical, sprinkled with short whitish hairs, like the leaf-surface of the food-plant; the mouth is slightly oblique. It was found on *Micromeria varia*, among which plant I took several specimens, at Guimar, at about 1200 ft. I also met with the species at Puerto Orotava, in February, and in May, and received three specimens from Mr. Eaton, taken in April 1904, at Cruz de Afur, and in the Forest de la Mina.

68. (3773) Coleophora Confluella Rbl.

Coleophora confluella Rbl. Ann. KK. Hofmus. VII. 278–9, 283 no. 63, Pl. $17 \cdot 15 \circ (1892)^{1}$: XXI. 44 no. 235 $(1906)^{2}$: Stgr-Rbl. Cat. Lp. Pal. II. 195 no. 3773 $(1901)^{3}$.

Hab. Canaries ¹⁻³—La Palma ^{1,3}: Pico del Berigoya, 1400–1500 m., 21. VIII. 1889 (Simony) ¹—Tenerife: Guimar, ⊕Helianthemum guttatum, 27. III, excl. 25. IX – 1. X. 1907 (Wlsm.); La Laguna, ⊕ Helianthemum guttatum, 3. V. 1907 (Wlsm.).

Larvae were common, in cases made of leaves (similar to those of helianthemella Mill.), on Helianthemum guttatum, and also on

Cistus monspeliensis. I found numerous cases at Guimar, at the end of March, from which I bred two specimens only at the end of September and the beginning of October. I have always found helianthemella an extremely difficult species to rear, under the conditions to which a travelling entomologist is restricted, and confluella presents similar difficulties, for I bred only the two specimens mentioned, although larvae were collected subsequently at La Laguna in the beginning of May.

68a, Coleophora sp.?

Three cases found on Adenocarpus foliolosus, at Guimar, 26th February, were extremely similar to those of confluella, and might have been taken for stray specimens from the Helianthemum, had I not observed traces of their feeding on the leaves. They were slightly smaller than the others, but would not feed in captivity and I failed to rear them.

69. (3815·1) Coleophora aegyptiacae Wlsm.

Coleophora aegyptiacae Wlsm, Ent. Mo. Mag. XLIII. 148 no. 3815·1 (1907) 1.

Hab. Algeria: Hammam-es-Salahin, $\bigoplus Salvia$ aegyptiaca, III – IV, excl. IV. Canaries—Tenerife: Santa Cruz, $\bigoplus Salvia$ aegyptiaca, 16. I – II. 1907.

Several cases of this Algerian species were found at Santa Cruz, at different dates in January and February, on Salvia aegyptiaca, but were not reared.

70. (3840·1) Coleophora teidensis, sp. n.

Antennae pale grey, with very faint paler annulations; basal joint smooth. Palpi greyish white; smooth, a few scales projecting from the end of the median, before the base of the short terminal joint. Head and Thorax pale silky grey. Forewings narrow; pale silky grey, without any ochreous or brownish scaling; a faint greyish white line, along the costa, is a little widened about the middle, but thence touches only the outer ends of the greyish costal cilia; other still fainter greyish lines running throughout the wing-length, one along the upper edge of the cell throwing three slender branches to the costa along the principal veins; one along the middle of the cell leaves the costa near the base, approaching and running parallel to the termen, another lying below it along the fold; cilia pale stone-grey. Exp. al. 13 mm. Hindwings very pale bluish grey; cilia pale stone-grey. Abdomen dark leaden grey. Legs whitish grey.

Type 3 (99026); 9 (99027) Mus. Wlsm.

Hab. TENERIFE: Puerto Orotava, 14. V. 1907; Tacaronte, 31. V. 1907; La Laguna, 5. VI. 1907. Three specimens.

The nearest approach to this species in our European lists is algidella Stgr., which it greatly resembles in colouration and in

the faint whitish longitudinal lines; it differs, however, decidedly in its much narrower forewings. I should place it between algidella Stgr. and murinipennella Dp.: its scarcely annulated antennae and more silky grey colour separate it from the latter.

71. (3852) COLEOPHORA ATLANTICELLA Rbl.

Taken commonly at Guimar, and bred from Senecio, Cytisus, Pinus, Mangifera, and Sonchus, bearing out my previous experience of the habits of the species in Europe and Morocco, where it is invariably a rubbish-feeder, among débris of spiders' webs, and frass of other larvae on numerous plants as enumerated

above.

36. (388) COSMOPTERYX Hb.

75. (3550·1) Cosmopteryx Coryphaea, sp. n. (Plate LII. fig. 10.) = Cosmopteryx sp. n. Wlsm. Ent. Mo. Mag. XXXVII. 237 (1901) ·.

Antennae pale buff, spotted with white along their outer sides. two black, and two white annulations occurring before a darker band, which precedes the four or five yellowish distal joints. Palpi white, with pale buff lateral lines throughout. Head olivaceous brownish, with a short central, and two longer lateral lines. Thorax olivaceous brown, with a central white line, and one along the inner edge of each of the tegulae. Forewings olivaceous brown to about three-fifths of their length, on which colour are five slender silvery white lines; one from the base of the costa, slightly diverging, and terminated below the costa at at about one-third; another, above it along the costa, slightly widened towards its outer end; a third, from the middle of the base, extending to the outer margin of the olive-brown space, whence a shorter, inverted, streak diverges, terminating opposite to the outer end of the first costal; the fifth streak is from the base, along the dorsum, and is rather shorter than the first costal;

beyond the brown space, and therefore a little beyond the middle of the wing, commences a pale lemon-yellow patch, which is continued toward the apex, bearing the following markings: first, two bright silver spots, each touching the brown preceding space, and each carrying a jet-black dot on the side opposite to it; beyond these, at a distance equal to about the middle of the wing, are two corresponding spots of bright silver scales, but with only one or two black scales attached, the yellow ground-colour extends between and beyond these, blending to creamy white along the costa and dorsum to the apex, the margins being separated by a short olive-brown dash reaching the extreme apex; cilia brownish grey. Exp. al. 9–10 mm. Hindwings pale grey; cilia brownish grey. Abdomen yellowish. Legs white, shaded externally with oblique olivaceous brownish bands.

Type \mathcal{S} (99029); \mathcal{Q} (99030) Santa Cruz, Mus. Wlsm.

Hab. Spain: Malaga: Malaga, 29. IV. 1901 (Wlsm.)¹. Canaries—Tenerife: Santa Cruz, 12–16. II. 1907. Eight specimens.

Nearest to *similis* Wlsm., but differing in the continuation of the yellow band beyond the outer pair of silver spots, giving the wing a much lighter appearance; in this respect it agrees with *quadrilineella* Chmb., but differs in having five white lines in the dark basal area of the wing, of these the subcostal, the median, and the dorsal arise from the base.

76. (3553) Cosmopteryx attenuatella Wkr.

n. syn. = flavofasciata E. Wlstn.; = lespedezae Wlsm.

Professor Rebel (l. c. 10) records and discusses flavofasciata E. Wlstn., of which I have one of the examples (7244) collected by von Hedemann in the Botanical Gardens at Puerto Orotava, 29. IV. 1895, and six taken by myself at Puerto Orotava, 14. V., and Guimar, 19. III - 12. IV. 1907. I have now re-examined Mrs. Wollaston's type from St. Helena, and am convinced that it is the same as the species identified by Rebel under this name from Tenerife, but the possession of more specimens has now enabled me to correct the synonymy as follows:—

attenuatella Wkr. (1864); = flavofasciata E. Wlstn. (1879); =lespedezae Wlsm. (1882)—thus proving that the species is

widely distributed.

77. (3555) Cosmopteryx Turbidella Rbl.

Cosmopteryx sp. Rbl. Ann. KK. Hofmus. IX. 18, 91-2 no. 183 (1894) . Cosmopteryx turbidella Rbl. Ann. KK. Hofmus. XI. 135-6, 147 no. 209. Pl. $3 \cdot 14 \ \Omega$ (1896)²: XXI. 44 no. 231 1906 ³: Stgr-Rbl. Cat. Lp. Pal. II. 185 no. 3555 (1901 ⁴).

Hab. Canaries 1-4—Tenerife 1-4: Guimar, 5. II - 17. III. 1907 (Wlsm.), 20. III. 1904 (Eaton), \oplus Parietaria vulgaris, 5. II, excl. 17-18. III. 1907 (Wlsm.); Puerto Orotava, \oplus Parietaria, excl. 15-25. III. 1904 (Eaton), 16-30. IV. 1895 (Hedemann)²; Forest de la Mina, 17. III. 1902 (Eaton); Cruz de Afur, 5. IV. 1904 (Eaton); Las Mercedes, 28. V. 1907 (Wlsm.), VI. (Cabrera); Barranco del Loro (nr. Realejo Alto), \oplus Parietaria arborea, 7. V, excl. 11-12. VI. 1907 (Wlsm.).

Cosmopteryx turbidella feeds on Parietaria vulgaris, near Guimar, in great abundance; it was found there by Mr. Eaton, who also observed the larvae where I have taken and bred it. An intimate acquaintance with the form of the mine caused me to suspect that a large, broad-leaved, shrub growing in the Barranco del Loro, above Realejo Alto, was Parietaria arborea;

and this turned out to be correct.

C. turbidella Rbl. differs from pulcherrimella Chmb. in the possession of a black dot, a little above the middle of the wing, contiguous to the golden metallic band which precedes the yellow fascia; also in having the silver apical streak undivided, whereas in pulcherrimella it is broken into two short lines; moreover, the outer golden fascia does not commence in a pure white costal spot, as in the somewhat smaller American species. After reexamining my series of pulcherrimella, collected in Madeira by Wollaston, with the addition of specimens subsequently received from Eaton, and my own from Tenerife, I am surprised to find that there is not a specimen of turbidella from Madeira. Mr. Eaton notes (MS., 16. IV. 1904) that "The Cosmopteryx so common at Guimar, and Puerto (de la Cruz) Orotava [i. e. turbidella Rbl.], was also plentiful on Parietaria, at Funchal, in the garden of the Carmo Hotel"; but his specimens of pulcherrimella were taken at "Funchal: at altitude of about 600 ft., 26. II. 1902: out of Eupatorium adenophorum Spreng.," one of the Compositae. This plant should be searched, but it is not a probable food-plant for pulcherrimella Chmb., which in the United States feeds on Pilea pumila, one of the Urticaceae.

Cosmopteryx turbidella is by no means consistent in the colour of the yellow fascia; this, in some specimens, is almost obsolete through the strength of the brownish suffusion; in others the colour is only slightly influenced in tone, while rarely it is of a clear orange-yellow, without partial shading or suffusion. I have again carefully compared all the specimens, without being able to detect any difference between the American and Madeiran

specimens of pulcherrimella.

VI. 1907 (Wlsm.).

Mr. White took a good specimen of this at Guimar, when collecting with me, at the end of March; I subsequently met

with a worn example, at La Laguna, in June.

38. (417) APHELOSETIA Stph.

=*Elachista (Tr. p.) Z., Stn., Stgr-Rbl., etc.

Type Phalaena Tinea argentella Cl. (Wstwd. 1840).

Aphelosetia Stph. Ill. Br. Ent. Haust. IV. 287 (1834); Wstwd. Syn. Gn. Br. Ins. 112-3 (1840).

ELACHISTA Tr. (C. ELACHISTA) Z. Isis 1839. 211, 212-3.

When describing *Elachista*, Treitschke [Schm. Eur. IX. (2), 177 (1833)] wrote as part of his generic diagnosis: "Die Raupen leben auf der Unterseite der Baumblätter oder minirend zwischen den Häuten derselben. Sie verpuppen sich in festen Hülsen." This restricted the possible type to species with such larval habits (i. e. Bucculatrix Z. and Phyllonorycter Hb.) with whose lifehistory Treitschke was acquainted, and rendered it impossible for any of the grass-mining species (Elachista Auct.) to be regarded as a potential type. Treitschke quotes the life-history of Bucculatrix frangulella Göze and Phyllonorycter (Lithocolletis) tremulae Z. from Fischer von Röslerstamm (in litt.), but he was personally acquainted with the larvae of *ulmifoliella* Hb. and blancardella (F., mespilella Hb. 272) Tr. Elachista Tr. must therefore sink as a synonym of Phyllonorycter Hb., and ulmifoliella Hb. should be taken as the type. Duponchel [HN. Lp. Fr. XI. 25, 499-502 no. 30 (1836)] cited complanella Hb. as the type of Elachista Tr., but Treitschke was unacquainted with the larva of complanella, and this species is not indicated as specially typical. Zeller's restriction to the grass-feeding species is also invalid for the same reason.

79. (3994·1) APHELOSETIA HYPOLEUCA, sp. n. (Plate LII, fig. 11.)

Antennae fuscous, the basal joint pale ochreous. Palpi whitish ochreous. Head and Thorax whitish ochreous, the latter faintly shaded with fawn-grey. Forewings pale ochreous (whitish ochreous if worn), sprinkled and suffused with fawn-brown, especially above the fold beyond the middle, with some deeper brownish fuscous shades, notably along the costa and about the tornus; three black spots, one below the costa at two-thirds; a smaller one, a little beyond and below it, about the end of the cell; a third, more conspicuous, on the fold at about half the winglength; a strong blackish shade-line runs along the middle of the brownish ochreous cilia. Exp. al. 8–9.5 mm. Hindwings rather dark leaden grey; cilia tawny greyish. Abdomen grey, anal tuft ochreous. Legs pale brownish ochreous, shaded with fuscous externally.

Type \eth (99036); Q (14312) Mus. Wlsm.

Hab. TENERIFE: Forest de la Mina, 17. III. 1902, 7. IV. 1904 (Eaton); Realejo, 7-10. V. 1907 (Wlsm.); Puerto Orotava,

14. V. 1907 (*Wlsm.*); La Laguna, 23. V. 1907 (*Wlsm.*); Las Mercedes, 29. V. 1907 (*Wlsm.*). Nineteen specimens.

Not uncommon, on the higher ground, in the barranco above Realejo and elsewhere; first taken by Mr. Eaton, in the forest of La Mina. It is very near to albidella Tngstr. (1847; =rhynchosporella Stn., 1848), but differs in the possession of two extra spots beyond the conspicuous plical one: the European species having no spot at the end of the cell or below the costa. Vein 5 is absent in both wings.

39. (417'01) POLYMETIS, gn. n. $(\pi o \lambda \dot{\nu} \mu \eta \tau \iota s = \text{of-many-counsels.})$

Type Polymetis carlinella Wlsm.

Antennae 3, slightly serrate towards apex; basal joint with strong pecten. Maxillary Palpi short. Labial Palpi smooth, usually dependent, but capable of upward movement; terminal joint shorter than median, rather obtusely pointed. Haustellum small. Head and face coarsely, almost roughly, scaled. Thorux Forewings evenly lanceolate: neuration 12 veins; 7 and 8 stalked, 7 to costa; 6 out of 7, to termen; 5 out of stalk of (6+7+8); rest remote, 3 slightly approximate to 4; 1° distinct, 1 furgate at base. *Hindwings* nearly $\frac{2}{3}$, tapering evenly to an acute apex; cilia $2-2\frac{1}{2}$: neuration 7 veins, 5 and 4 coincident; 6 and 7 stalked, enclosing apex; 2 remote from 3, which is somewhat approximate to (4+5); above 5 the discoidal recedes to radius. Abdomen smooth. Legs, hind tibiae hairy.

Almost corresponding in neuration with some species of Aphelosetia Steph. and Stagmatophora HS.; separated from the former by the basal furcation of vein 1 of the forewings, as well as by the shorter and less recurved palpi, and from the latter by the same characters, and by the coincidence of veins 5 and 4 of the hindwings. The habits of the larva afford additional reason for separating Polymetis from Aphelosetia (Elachista Auct.), of which the larvae of all known species feed on the Gramineae, or

Cyperaceae.

80. (3920.1) Polymetis Carlinella, sp. n. (Plate LII. fig. 13.)

Antennae and Palpi whitish cinereous. Head white. Thorax whitish cinereous. Forewings white, profusely and evenly dusted throughout with pale greyish brown scales; the outer half of the cilia whitish cinereous. Exp. al. 10-11 mm. Hindwings grey; cilia pale brownish cinereous. Abdomen greyish. Legs whitish, with faint greyish shade-bands on their outer sides.

Type \mathcal{E} (99037); \mathcal{Q} (99038) Mus. Wlsm.

Hab. Tenerife—Tacaronte, and Guimar, ⊕ sup. Carlina salicifolia, 19. II – III, excl. 13. III – 23. IV. 1907; Puerto Orotava, 27. IV. 1907. Eight specimens.

The larva feeds in mines, reminding one of those of the bramble-feeding *Tischeria marginea* Hw. on the upper surface of leaves of *Carlina salicifolia*. I found it near Tacaronte, at Guimar, and near Orotava—seven specimens were bred and one captured.

40. (274'1) MENDESIA Joannis.

MENDESIA Joann. Bull. Soc. Ent. Fr. LXXI: 1902. 230-1 (1902); Mendes Brotéria III. 249-51 (1904).

81. (2343·2) Mendesia symphytella, sp. n. (Plate LII. fig. 14.)

Antennae brownish fuscous; basal joint white, with strong pecten. Palpi slightly recurved, white; terminal joint less clothed, and therefore apparently rather more slender than median. Head coarsely scaled above; white. Thorax smooth, white. Forewings white, sparsely dusted with brownish scales; a brown spot in the fold at about half the wing-length, and another at the end of the cell; a brown streak along the termen, running out through the white apical cilia; cilia white, very sparsely dusted with brown along their base. $Exp.\ al.\ 12-14$ mm. Hindwings of the σ white; of the σ inclining to greyish; cilia of both sexes yellowish white. Abdomen greyish fuscous, except along the margins of the segments. Legs white; hind tibiae with long white hairs.

Type ♀ (99045); ♂ (99046) Mus. Wlsm.

Hab. Tenerife: Santa Cruz, 12. I - 10. II. 1907, ⊕ Symphytum sp., 7-25. I, excl. 25. I - 20. II. 1907 (Wlsm.); Forest de la Mina, 17. III. 1902 (Eaton); Guimar, 19. III - 10. IV. 1907 (Wlsm.); La Laguna, 1-6. IV. 1904 (Eaton). Thirty-three

specimens.

Twelve specimens were bred from larvae, found at Guimar, mining leaves of Symphytum; the mine almost undistinguishable from that of Acrocercops scalariella Z., but the pupa enveloped in a white, silken, rather flat, ovate cocoon. Mr. Eaton caught a single specimen of this species in the Forest de la Mina, in 1902; in 1904 he met with it again, at La Laguna, and I took it on the wing at Santa Cruz and Guimar.

41. (415) PERITTIA Stn.

82. (3919·2) Perittia cedronellae, sp. n. (Plate LII. fig. 12.)

Antennae tawny fuscous above, pale cinereous beneath; a pale spot at the outer end of the short, and rather thickened, basal joint. Palpi slender, drooping; tawny fuscous. Head dull yellowish white, the face shaded with fuscous. Thorax tawny fuscous. Forewings tawny fuscous, with some faint pale sprinkling; an oblique yellowish white dorsal streak, arising at

about one-fourth, extends across the fold to the cell; beyond the middle of the dorsum is another, yellowish white, upright streak, broad at its base, slightly inverted, and attenuate to its apex on the cell; this is succeeded by an ill-defined, and much diffused, streak along the termen; a dark fuscous line runs through the tawny greyish cilia, falsely indicating a tornus, more defined than in the wing itself. Exp. al. 6.5-7 mm. Hindwings dark grey; cilia tawny greyish. Abdomen greyish fuscous. Legs yellowish white, broadly banded on tibiae and tarsi with dark tawny fuscous.

Type 3 (99047); 2 (99048) Mus. Wlsm.

Hab. TENERIFE: Santa Cruz, 3000 ft.,

Cedronella triphylla, 3. I, excl. 24. I - 1. II. 1907 (Wlsm.); Puerto Orotava, 10. III. 1904 (Eaton); Cruz de Afur, 10. III. 1904 (Eaton). Fifteen

specimens.

The larva feeds, in December and January, in a broad blotchmine, on leaves of Cedronella triphylla, and is abundant at the head of the Barranco del Bufadero, near Santa Cruz, and probably on all the high ground, where this plant occurs, along the outskirts of the forests of Erica arborea. Mr. Eaton met with the species near the same locality, in 1904, and also in the Barranco Martianez, Puerto Orotava.

The Tenerife species of *Perittia*, here described, have the palpi slightly longer than those of obscurepunctella Stn., but this slight difference is not of generic value.

83. (3919.3) PERITTIA LAVANDULAE, Sp. n.

Antennae fuscous. Palpi fuscous, tipped with whitish. Head hoary whitish, with fuscous speckling. Thorax fuscous, with some whitish scales on the tegulae. Forewings dark fuscous, profusely sprinkled with rather yellowish white scales, by concentration of which the dorsal streak arises at one-fourth, pointing outward, and diffused upward to the costa; a larger, upright, streak arises before the tornus and extends nearly to the costa, a further patch spreading over the upper half of the termen and apex; a line of dark fuscous scales runs through the greyish fuscous cilia. Exp. al. 4.5-6 mm. Hindwings and cilia greyish Abdomen dark fuscous. Legs whitish, broadly banded with dark tawny fuscous on the tibiae and tarsi.

Type σ (99071); Ω (99072) Mus. Wlsm.

Hab. Tenerife: Santa Cruz, 14. I - 21. II. 1907, \(\operatorname{A}\) Lavandula abrotanoides, 20. I - 22. II, excl. 13. II - 28. III. 1907; Guimar, 28. II. 1907; La Laguna, \oplus Lavandula staechas, 3. VI, excl. 19. VII. 1907. Thirty-six specimens.

The larva is common, at Santa Cruz, on Lavandula abrotanoides, hollowing out the ends of the slender leaflets, and leaving them bleached, when passing from one to another (after the manner of the larvae of Epermenia on Umbelliferae); it also feeds on Lavandula staechas.

It is extremely difficult to describe the differences between this species and *cedronellae*: its smaller size, more sprinkled appearance, and slightly yellower-white markings may alone be relied on to separate them.

I have, what I believe to be, yet a third, intermediate, species of *Perittia*, (bystropogonis), from Guimar, feeding on *Bystropogon plumosus*, in March, and emerging towards the end of April.

Hab. Tenerife: Guimar, \oplus Bystropogon plumosus, 27. III,

excl. 21–26. IV. 1907. Six specimens (99076–81).

42. (384) SCYTHRIS Hb.

84. (3478·02) Scythris arachnodes, sp. n. (Plate LII. fig. 16.)

Antennae black. Palpi slender, porrect; hoary greyish, mixed with black. Head and Thorax black; face greyish. Forewings short, obtusely lanceolate; black, a few greyish white scales at the base, and two transverse bands of the same, one before, the other beyond the middle; the first narrower than the second, and running a little obliquely outward from the costa; the second moderately straight, both being ill-defined, with a few scattered whitish scales between them, others forming a patch at the apex; cilia greyish fuscous. Exp. al. 7-10 mm. Hindwings dark leaden grey; cilia greyish fuscous. Abdomen steely grey. Legs greyish fuscous, the tarsi shaded with black.

 $Type \ 3 \ (99082); \ \ (99083); \ \ \oplus \ (99084) \ \mathrm{Mus. \ Wlsm.}$

Hab. Tenerife: Santa Cruz, 12-20. II. 1907 (Wlsm.), 4. IV. 1904 (Eaton), ⊕ in webs on rocks, 6. I, excl. 15. II - 28. III. 1907 (Wlsm.); Cruz de Afur, 5. IV. 1904 (Eaton); Guimar, ⊕ in webs on rocks, 1. III - 4. IV, excl. 11. VIII. 1907 (Wlsm.).

Twenty-seven specimens.

The larva feeds, probably on small lichens, on the surface of rocks, and rough stones in walls, and is very widely distributed in the Island, where its webs are to be seen forming numerous small patches on the face of almost every rock by the roadside. They have the appearance of rather opaque spiders' webs, and as they endure long after the moth has left them they are much more numerous than the larvae themselves. Nearly allied to bubaniae Wlsm. [Ent. Mo. Mag. XLI. 6–7 no. 3478·1 (1907)], but smaller, and the fasciae are much more distinct.

85. (3533·1) Scythris Petrella, sp. n. (Plate LII. fig. 17.)

Antennae greyish fuscous. Palpi slender, porrect; ash-grey. Head and Thorax ashy grey. Forewings greyish fuscous, mottled with ashy white, the base sprinkled with ashy white scales; an outwardly angulate, ill-defined fascia at two-fifths, followed by more sprinkled scales, especially towards the costa, the whole

outer third of the wing mottled with the same, a spot at the end of the cell, a costal patch before the apex, and a streak along the termen being of the plain dark ground-colour; cilia ashy greyish. Exp. al. 8-9 mm. Hindwings grey; cilia brownish grey. Abdomen fuscous. Legs pale ashy grey.

Type ♂ (99085) ♀ (99086) Mus. Wlsm.

Hab. Tenerife: Puerto Orotava, 23–30. IV. 1907; Las Mercedes, 29. V. 1907; La Laguna, 5. VI. 1907. Twelve specimens. The distribution of the ashy white scaling varies considerably,

The distribution of the ashy white scaling varies considerably, and in some specimens occupies a much larger proportion of the wing-surface than in others. It appears to be more variable than the larger, and perhaps allied, *cicadella Z.*, and is paler and less uniform in its ill-defined marking than *arachnodes*.

86. (3536) Scythris fasciatella Rgt. (Plate LII. fig. 15.) = *roscidella Rbl. (nec Z.).

Butalis fasciatella Rgt. Bull. Soc. Ent. Fr. XLIX. (5 s. X: 1880). pp. exxi-ii (1881). *Blastobasis *roscidella Rbl. Ann. KK. Hofmus. IX. 18, 90 no. 177 (1894). XXI. 44 no. 219 (1906). Butalis fasciatella Sbld. Dentsche Ent. Zts. Iris XI. 319 (1898). Scythris fasciatella Stgr-Rbl. Cat. Lp. Pal. II. 183 no. 3536 (1901).

Antennae cinereous beneath, fuscous above. Palpi whitish cinereous. Head and Thorax pale cinereous, a brownish band crossing the latter, including the outer part of the tegulae. Forewings hoary whitish, dusted with fuscous and pale rust-brown scales; a much sprinkled basal patch, extending to one-third, is obliquely margined outwardly by a band of the pale groundcolour, the sprinkling being condensed in a small costal spot near the base, and in a costal shade a little beyond this-both accompanied by rust-brown; an oblique fuscous fascia, about the middle. is shaded with rust-brown along its ill-defined outer side and on the costa, the paler apical area beyond it much sprinkled and mottled with the same colours, in which a fuscous, condensed, spot above the tornus is distinguishable; cilia greyish fuscous, with some hoary scales. Exp. al. 10.5-11 mm. Hindwings brownish grey; cilia pale greyish fuscous. Legs hoary whitish, the hind tibiae with two greyish fuscous bands across their outer sides; the hind tarsi also suffused with fuscous externally.

CT. σ (99087); Ω (99088); Ω (99089) Mus. Wlsm.

Larva brownish grey; head pale brownish; a pale, ill-defined, dorsal line, interrupted by brownish fuscous spots on each of the abdominal somites; all the somites laterally shaded with brownish fuscous, and stippled with minute pale ocellated dots; underside, up to the spiracular line, pale whitish ochreous; thoracic legs dotted with fuscous. Long. 12 mm.

Hab. Spain ^{1, 4-5}: Valencia: Alicante, ⊕ ...? ..., excl. 15. XI. 1879 $(Rgt.)^{1}$: Andalusia ⁴⁻⁵: III ⁴. Canaries ²⁻³—Tenerife: IV. 1885 $(Leech)^{2}$; Puerto Orotava, 26. IV − 10. V. 1907 (Wlsm.),

⊕ Salsola oppositifolia, 27. IV, excl. 19. V – 2. VI. 1907 (Wlsm.), ⊕ Atriplex parvifolius, 10. V, excl. 3. VI. 1907 (Wlsm.).

When describing fasciatella, Ragonot states that he took and bred several specimens, but omits to mention the food-plant. I found this species on the wing, and the larva feeding among shoots of Salsola oppositifolia, and on Atriplex parvifolius in a slight web, in April and May; the moths emerged in May and June. This is the species wrongly identified by Rebel as "Blastobasis roscidella Z.", which, apart from the generic differences, it does not greatly resemble. I fear the specimen I sent him must have been a very poor one. The type of Blastobasis roscidella is in the Zeller Collection, and I have also a Cotype of Butalis fasciatella received from the late M. E. Ragonot.

43. (383) EPERMENIA Hb.

Many years ago I received a considerable number of larvae of

this species from Dr. John Lowe, who wrote as follows:—

"The larvae occur in countless myriads on the Willow, Poplar, and 'Till' trees (Laurel: Oreodaphne foetens). They spin a fine silken web over the entire tree, even to its ultimate branches, which makes them look white and silvery. The underwood and stones at the base are also covered with the silk tissue, which is so closely woven that there are no visible openings. I was able to strip off pieces five or six feet in length.".... "It is just possible that there may be more than one species, but I am doubtful about this. If it is so one will be found in the box, with a pin through it, which I took from Salix—the rest were from Oreodaphne. I am sending you some of the silk, which is most remarkable. The brushwood under the trees was completely covered by it, also the grasses and large stones. The tree-trunks were so closely covered that one could not see even a pinhole on the smooth trunks of the 'Till'—every branch was covered, and scarcely a leaf remained on any of the infested trees, which were 60 or 70 ft. high. At the base of the trunks the appearance of the web was most singular—large reticulations, like pulmonary cells, seemed to open one into the other, but on closer examination the apparent openings were found to be closed by a membrane of perfect continuity, but so transparent that until something was passed through it one could not perceive that it existed." (Dr. Lowe, in litt., 29. IV., 20.V. 1893.)

I first met with Hyponomeuta gigas on three large trees of Salix canariensis, at the first branching of the large barranco above Realejo Alto: the ends of the branches were entirely covered with the colonies of larvae, in dense web, having a seriously denuding effect upon the foliage. Subsequently I found it, in less abundance, on Populus alba, in the Eucalyptus avenue, running north-east from La Laguna. There is no difference between the specimens reared from Salix and Populus respectively; the larvae also were undistinguishable. Rebel originally described gigas (l. c. 1) as sexually dimorphic, having "alis plumbeis, anterioribus σ punctis nigris triseriatis, φ innotatis"; subsequently, however, he came to the conclusion that both sexes occurred in both forms, and that the spotless form was characteristic of Gran Canaria, appearing

only as an aberration in Tenerife. It may be convenient to name the spotless form innotata, var. n., and then to enumerate in

series each variety as represented in my collection.

I have 129 (=gigas 93+36 innotata) specimens, of which 103 (=gigas 91+12 innotata) are from Tenerife, and 26 (=gigas 2+24 innotata) are from Gran Canaria. The series of 103 specimens from Tenerife is composed of 91 (= $66 \ \color \color$

The 26 (=9 $\eth \eth + 17 \circlearrowleft \lozenge)$ specimens from Gran Canaria were bred by Dr. Lowe from *Ocotea foetens*; 24 (9 $\eth \eth + 15 \circlearrowleft \lozenge)$ are

innotata, while $2 (\mathcal{Q} \mathcal{Q})$ are gigas.

46. (424) PHYLLONORYCTER Hb.

Extremely abundant at Santa Cruz: the fallen leaves were

crowded with mines at Xmas, 1906.

93. (4180) Phyllonorycter cytiselllus Rbl.

Lithocolletis cytisella Rbl. Ann. KK. Hofmus. XI. 140–1, 147 no. 217. Pl. $3\cdot 17$ –17° (1896)¹: XXI. 44 no. 242 (1906)²: Stgr-Rbl. Cat. Lp. Pal. II. 215 no. 4180 (1901)³.

Hab. Tenerife ¹-³: La Laguna, ⊕ Cytisus proliferus, 13. I, excl. 16. I − 8. II. 1907 (Wlsm.); Guimar, ⊕ Cytisus proliferus, 26. II, excl. 3-25. III. 1907, 7. IV. 1907 (Wlsm.); Puerto Orotava, 11-26. IV. 1895 (Hedemann)¹, 9. V. 1907 (Wlsm.); Las Mercedes, 29. V. 1907 (Wlsm.).

Common: a long series taken among, and bred from, Cytisus proliferus. It is very variable, some forms approaching juncei.

94. (4180·1) Phyllonorycter Juncei, sp. n.

Antennae and Palpi white. Head white, mixed with golden brownish. Thorax golden brownish, with white streaks at the sides, and posteriorly. Forewings shining, golden brown, with five costal, and two dorsal, white streaks, more or less plainly indicated; the first costal is at about half the wing-length, and further removed from the second than the others are from each other; the first dorsal is larger than the first costal, commencing before it, but approaching it at its apex; the second dorsal is opposite to the second costal; there is also a white basal streak, sometimes produced as far as the first pair, and partially connected with a small white dorsal streak; the outer half of the wing is thickly studded with black scales, which tend to form dark inner margins to the first and second costal, and to the second dorsal streaks, also an outer margin to the inverted costal streak before the apex; there is a conspicuous, elongate patch of similar black scales, also before the middle, forming an inner margin to the first dorsal streak; terminal cilia golden brown at their base, with a dark line dividing this from their paler outer ends. Exp. al. 7.5-9 mm. *Hindwings* pale grey; cilia pale brownish grey. Abdomen greyish. Legs white.

Type ♀ (99090); ♂ (99091) Mus. Wlsm.

Hab. Tenerife: Villa Orotava, 6. V. 1907; Puerto Orotava, ⊕ Genista stenopetala, 8. V, excl. 13-16. V. 1907; La Laguna, ⊕ Spartium junceum, 21. V, excl. 23. V - 6. VI. 1907. Seventy-

eight specimens.

This is apparently allied to cytisellus Rbl., and, like it, is also very variable in the intensity of its markings, which in some specimens are more or less evanescent, but, whereas in cytisellus the white so strongly predominates as to overrun the wing and leave golden markings, in juncei the golden ground predominates, leaving white markings. I have a long series of bred specimens of both species, and can never be at a loss to distinguish them.

I first found *juncei* in the garden behind the Hotel Vittoria, Villa Orotava, flying freely about *Genista stenopetala*, and afterwards bred it from leaves of the same, gathered at Puerto Orotava; but it was even more abundant on *Spartium junceum*, by the side of the road from La Laguna to Tegeste, where, in one spot only, for about 100 yards, almost every leaf of these plants was affected by the larvae. The species is described from specimens bred from *Spartium junceum*.

95. (4207·1) Phyllonorycter foliolosi, sp. n. (Plate LIII. fig. 8.)

Antennae white, with blackish annulations. Palpi white. Head and Thorax pale golden brown. Forewings pale golden brown, with four costal and three, or four, more obscure, white dorsal streaks; the first two pairs opposite, and frequently appearing as two fasciae by meeting each other, a slender whitish streak sometimes connecting them along the middle; between the white streaklets, as well as towards the base, the wing is plentifully bestrewn with minute black scale-points; cilia mixed golden and whitish, becoming greyish along the dorsum. Exp. al. 4–5.5 mm. Hindwings and cilia pale grey. Abdomen grey, anal tuft ochreous. Legs yellowish white.

Type ♂ (99092); ♀ (99093) Mus. Wlsm.

Hab. Tenerife: Guimar, 25. II - 6. III. 1907, \bigoplus Adenocarpus foliolosus, 26. II, excl. 1-10. III. 1907 (Wlsm.); La Laguna, 25. III. 1904 (Eaton), 23. V - 9. VI. 1907, \bigoplus Genista canariensis, 18. V, excl. 5-15. VI. 1907 (Wlsm.). Fifty-three specimens.

The larva feeds in the tiny leaflets of Adenocarpus foliolosus, at Guimar, at about 2000 ft. above sea-level, sometimes giving to the branches a whitened appearance, through the bleaching of innumerable leaves; I found the same species later, at La Laguna, on Genista canariensis, where Mr. Eaton had taken it in March 1904.

The species is allied to parvifoliellus Rgt., but differs in the more numerous costal streaks.

47. (420'01) ACROCERCOPS Wlgrn.

n. syn.=Conopomorpha Meyr.; = Dialectica Wlsm.

Type 1. Tinea brongniardella F. (Wlgrn. 1881). Acrocercops Wlgrn. Ent. Tdsk. II. 95 (1881).

Type 2. Conopomorpha cyanospila Meyr. (Meyr. 1886). Conopomorpha Meyr. Tr. NZ. Inst. XVIII. 183 (1886): Pr. Lin. Soc. NSW. XXXII. 49, 54-61 no. 4 (1907).

Type 3. Gracilaria scalariella Z. (Wlsm. 1897). Dialectica Wlsm. Pr. Z. Soc. Lond. 1897. 150-1 no. 93.

In his recent paper [Pr. Lin. Soc. NSW. XXXII. 47-68 (1907)] Meyrick has removed the groups of Gracilaria and Zelleria from the Tineidae to the Plutellidae, assigning now "more importance to the smooth posterior tibiae which are a normal attribute of those two groups, than to the rough head which is a frequent character-Moreover, whilst folded maxillary palpi are peculiarly characteristic of the Tineidae, the simple porrected maxillary palpi of the Gracilaria group are so similar to those of the Plutella group, and so different from those of any other *Tineina*, that they would seem to indicate real affinity." He concludes from his study of the Gracilaria group that "Coriscium Z. cannot be maintained as a distinct or natural genus, the scaling of the palpi being subject to much variation, and not according with true affinity. On the other hand," he has "found it practicable to use the scaling of the legs to break up the whole of the species thus thrown together into four groups which are both natural and strictly definable, and since the number of species known is already very large and destined to be much larger," he has "thought it conducive to clearness to establish them as genera." Cyphosticha Meyr. and Conopomorpha Meyr., having "Posterior tibiae with bristly hairs above," are separated from Gracilaria Hw. and Macarostola Meyr., with "Posterior tibiae smoothscaled." Dialectica Wlsm. is sunk as a synonym of Conopomorpha Meyr.; but brongniardellum F. also has "Posterior tibiae bristly above [Meyr. HB. Br. Lp. 749 (1894)], for which reason Wallengren removed it from Coriscium Z., making it the type of Acrocercors Wlgn. (1881), described as having "Tibiae postice setosae," and, consequently, Conopomorpha must also sink as a synonym.

96. (4082·1) Acrocercops Hedemanni Rbl.

Gracilaria hedemanni Rbl. Ann. KK. Hofmus. XI. 136-7, 147 no. 211. Pl. 3 · 15 ♂ (1896)¹: XXI. 44 no. 239 (1906)²: Stgr-Rbl. Cat. Lp. Pal. II. 207 no. 4067 (1901)³.

Hab. Madeiras—Madeira: The Curralhino, Funchal, 9. IV.

1902 (*Eaton*). Canaries ¹¬³—TENERIFE ¹¬³: Guimar, 2. III. 1907 (*Wlsm.*); La Laguna, 17. III. 1902 (*Eaton*); Forest de la Mina, 2500−2800 ft., 7. IV. 1904 (*Eaton*); Puerto Orotava, 23. IV. 1907, ⊕ *Malva parviflora*, 23. IV, excl. 11-14. V. 1907 (*Wlsm.*); La Matanza, 2. V. 1895 (*Hedemann*)¹; Las Mercedes, 29. V. 1907 (*Wlsm.*).

The publication of Prof. Rebel's figure of hedemanni prevented me from describing a very closely allied species, found at Tangier in 1901. I have now a considerable series of each, and am acquainted with their larvae. Both feed on species of Malvaceae, making conspicuous blotches on the upper sides of the leaves, and in both instances the larvae assume, before pupating, the beautiful transverse bands of scarlet, or rich carmine, so well known in Acrocercops brongniardellum F.

The Tenerife species is exceedingly common, feeding on Malva parviflora everywhere, and on Lavatera arborea in gardens, at Orotava and elsewhere. I have received hedemanni also from Funchal, Madeira (Rev. A. E. Eaton); there is no difference

between the Tenerife and Madeira specimens.

(4032.2) Acrocercops Malvacea, sp. n.

=*hedemanni Wlsm. (nec Rbl.).

Dialectica sp. n. Wlsm. Ent. Mo. Mag. XXXVII, 236 (1901) ¹. Gracilaria *hedemanni Wlsm. Ent. Mo. Mag. XXXIX, 181 (1903) ².

Hab. Morocco: Tangier 1-2, ⊕ Malva sp. 1, Lavatera olbia 2, ⊕ [Malva? sp. ?], XII, excl. 1-11. I. 1902, ⊕ 13. IV, excl. 29. IV - 9. V. 1901. Thirty-six specimens. Type ♂ (88655); ♀ (88669); ⊕ (88688) Mus. Wlsm. When recording Gracilaria hedemanni from Morocco [Ent. Mo. Mag. XXXIX.

When recording Gracilaria hedemanni from Morocco [Ent. Mo. Mag. XXXIX. 181 (1903)], I was somewhat misled by the absence of a pale basal patch in Rebel's figure. Such a patch is distinctly present in hedemanni, but barely traceable or entirely absent from the Tangier insect; moreover the dorsal spot beyond the central fascia is also absent from what I may now call Acrocercops malvacea, sp. n. There is also a slight difference in the larvae: in malvacea the scarlet transverse bands are shorter, extending less far laterally, and the head is brown—not blackish as in hedemanni. I recorded the food-plant as Lavatera olbia (Ent. Mo. Mag. XXXIX. 181), but I am unable now to verify this by reference to preserved specimens, which is to be regetted, as I had previously [Ent. Mo. Mag. XXXVII. 236 (1901)] thought the plant "a very large mallow". It was a tall Malvaceous plant, sometimes seven or eight feet high, with broad rounded leaves and white, or lilac, flowers.

Hab. WC. ASIA. C–S. EUROPE: \bigoplus Juglans—Spain: Granada: Sierra Nevada, 3 VI. 1901 (Wlsm.). Madeiras ⁵⁻⁶— Madeiras ⁵: San Antonio da Serra (Wollaston) ⁵; Rabaçal, 3430 ft., 29. IV. 1904 (Eaton). Canaries ³⁻⁷—Tenerife ³⁻⁷: IV. 1885 (Leech) ⁴; La Laguna, \bigoplus Laurus canariensis, 19. V, excl. 9. VI – 21. VII. 1907 (Wlsm.); Taganana, 9. VIII. 1889 (Simony) ³.

Prof. Rebel records specimens taken by Professor Simony, above Taganana, among Woodwardia radicans; he subsequently recognised a worn specimen, in my own collection (61049), received from the late Mr. J. H. Leech, from Tenerife. I have now succeeded in breeding a few examples from larvae forming conspicuous cones on Laurus canariensis, collected in the neighbourhood of La Laguna and Tegeste: after comparing them with a series bred from leaves of Juglans, at Cannes, I am quite unable to separate them, but I failed to find any larvae on Juglans in Tenerife, although some trees grew at no great distance from the spot where most of my larvae were taken.

99. (4057·1) Gracilaria staintoni Wlstn. (Plate LIII. fig. 14.) Gracilaria staintoni Wlstn. Ann-Mag. NH. (3 s.). I. 122 (1858)¹: Wkr. Cat. Lp. BM. XXX. 854 no. 24 (1864)²; Wlsm. Tr. Ent. Soc. Lond. 1894. 538, 555 no. 62 (1894)³; Stgr-Rbl. Cat. Lep. Pal. II. 206 no. 4049 (1901)⁴.

Antennae pale brownish yellow. Labial Palpi white, smeared with tawny reddish on the outer side of the terminal joint, and toward the apex of the median. Maxillary Palpi white, tipped with tawny reddish. Head pale yellowish brown; face whitish. Thorax bright golden yellow above; the tegulae reddish brown. Forewings very long and narrow; shining, bright, pale golden yellow, with a purplish lilac suffusion spreading over the dorsal half and becoming rather darker across the apex; at the upper edge of the purplish shade are two or three slight projections of a rather more intense colour, and, on either side of the middle of the costa above them, are one or more minute black dots; cilia reddish purple above the apex, reddish ochreous below it, dark tawny grey along the dorsum. Exp. al. 13-14 mm. Hindwings shining, leaden grey; cilia tawny grey. Abdomen leaden grey, silvery white beneath. Legs pale grey, the tarsi fading to whitish, and very faintly spotted.

Wlsm.

Hab. Madeiras ¹⁻¹ — Madeira ¹⁻⁴: Funchal, 16. IV. 1904 (*Eaton*); The Mount, $1855 \, (Wollaston)^{1,3}$. Canaries — Tenerife: Las Mercedes, 30. III. 1904 (*Eaton*); Taganana, 27. V. 1907; Agua Garcia, Tacaronte, 31. V. 1907 (*Wism.*); La Laguna, ⊕ *Laurus canariensis*, 19. V, excl. 12. VI. 1907 (*Wism.*).

This species was captured at Taganana, and at Água Garcia, near Tacaronte, and subsequently bred from larvae feeding in large cones on the leaves of *Laurus canariensis*, which were undistinguishable from the cones made by *roscipennella* on the same tree. Mr. Eaton took this species at Funchal, and at Las Mercedes, in 1904.

100. (4057·2) Gracilaria schinella, sp. n. (Plate LIII. fig. 13.)

Antennae pale brownish ochreous, faintly dark-barred above. Palpi brownish ochreous, smeared with rust-brown externally. Head and Thorax brownish ochreous; the tegulae touched with purplish. Forewings pale ochreous, suffused with reddish lilac, more strongly at the base of the costa than elsewhere, and notably less on a pale, elongate, mediocostal patch extending to the fold, which, however, like the rest of the wing-surface, is distinctly iridescent; the more suffused portions exhibit every possible variety of iridescence, from purple to green, and cupreous, according to the incidence of light; there is a purplish shade in the cilia below the apex, but the dorsal cilia are pale, iridescent, bronzy greyish. $Exp.\ al.\ 11-14\ mm.\ Hindwings\ \frac{1}{2}$; pale leaden

grey; cilia iridescent, greyish cupreous. Abdomen grey, anal tuft ochreous. Legs cincreous; the femora and tibiae of the anterior and median pairs thickly clothed with tawny reddish fuscous.

Type d (99130); Q (99131) Mus. Wlsm.

Hab. Tenerife: Santa Cruz, 3. I. 1907, ⊕ Schinus molle, 27. XII – 11. I, excl. 22. I – 7. III. 1907. Fifteen specimens.

This species is exceedingly common at Santa Cruz, where the young larva mines the leaflets of *Schinus molle*. It subsequently forms a blister, like that of a *Phyllonorycter*, and eventually rolls a whole leaflet into a compact cone, sometimes pupating within it, but frequently leaving it and forming a smooth, silken cocoon under another leaf. It is remarkable that this species should have escaped observation so long, the tree on which it lives being so commonly introduced in all parts of the south of Europe. It is probably not indigenous in Tenerife, but, if this be the case, it is one of the very rare instances of the introduction of an exotic insect with an imported plant.

101. (4057·3) Gracilaria aurantiaca Wlstn. (Plate LIII. fig. 12.)

Gracilaria? aurantiaca Wlstn. Ann-Mag. NH. (3 s.). I. 122 $(1858)^1$; Wkr. Cat. Lp. BM. XXX. 854 no. 25 $(1864)^2$. Blastobasis (?) aurantiaca Wlsm. Tr. Ent. Soc. Lond. **1894**. 538, 552 no. 53 $(1894)^3$; Stgr-Rbl. Cat. Lp. Pal. II. 164 no. 3066 $(1901)^4$. Gracilaria sp. Rbl. Ann. KK. Hofmus. XXI. 39, 44 no. 238 $(1906)^5$.

Antennae ochreous, faintly barred above with chestnut-brown. Palpi ochreous, the median joint chestnut-brown on its outer side. Head ochreous. Thorax brownish ochreous; tegulae tinged with reddish. Forewings rich brownish ochreous, suffused with tawny red toward the apex; with a broad, rich tawny red, triangular patch, commencing at the base of the costa and extending two-thirds the length of the wing, its lower angle slightly crossing the fold before the middle; from the tornus arises an inverted, short, diffused streak of the same colour, the cilia also are tawny reddish, except on the costa before the apex, where they are pale cinereous. Exp. al. 11–15 mm. Hindwings shining, pale grey; cilia pale cinereous. Abdomen cinereous. Legs pale cinereous, unspotted.

Madeiras ^{2, 5, 7, 9}—Madeira ²⁻⁵: The Mount (Wollaston) ⁴. Canaries ^{5, 7, 9}—Tenerife ⁵: Santa Cruz, ⊕ Convolvulus althaeoides, 10. I, excl. 22. I – 10. III. 1907 (Wlsm.); Guimar, 2. III. 1907 (Wlsm.); Puerto Orotava, 23. IV. 1895 (Hedemann) ⁵. UNITED STATES ^{3, 5-9}: ⊕ Ipomoea, Pharbitis ⁹. HAWAIIA ⁹. AUSTRALIA ⁹. N. ZEALAND ⁹.

Common on various species of Convolvulus: I have recognised the mines on Convolvulus floridus, and bred it from C. althaeoides.

The record of the occurrence of "Phyllobrostis daphneella Stgr." in the Madeiras [Wlsm. Tr. Ent. Soc. Lond. 1894. 538, 555 no. 66] must be corrected: examining again the fragment, thus identified at the time, I find it to be a remnant of Bedellia somnulentella Z., which Stainton had already recorded from Madeira.

50. (426) TISCHERIA Z.

103. (4210·1) TISCHERIA TANTALELLA, sp. n.

Antennae pale fawn-ochreous. Palpi, Head, and Thorax pale fawn-ochreous. Forewings pale fawn-ochreous, thickly sprinkled with yellowish, and some fawn-brownish, scales, the latter condensed in a narrow streak along the base of the costa, and in a small, but conspicuous tornal spot; cilia brownish grey. Exp. al.

8 mm. *Hindwings* pale grey; cilia brownish grey. *Abdomen* grey above, pale yellowish at the sides and beneath. *Legs* shining, fawn-whitish.

Type ♂ (98990) Mus. Wlsm.

Hab. TENERIFE: Guimar, 2. III. 1907. Unique.

The most persistent searching failed to secure a second specimen; there was no oak anywhere near where it occurred. It appears to be more nearly allied to North American than to European species.

104. (4215) TISCHERIA LONGICILIATELLA Rbl.

Tischeria longiciliatella Rbl. Ann. KK. Hofmus, XI. 141–2, 147 no. 218 (1896) ¹: XXI. 44 no. 243 (1906) ²: Stgr-Rbl. Cat. Lp. Pal. II. 217 no. 4215 (1901) ³.

Hab. TENERIFE ¹⁻³: Villa Orotava, ⊕ Rubus fruticosus, 19. II, excl. 27. II - 22. III. 1907 (Wlsm.); Guimar, 28. II - 19. III. 1907, ⊕ Rubus fruticosus, 27. II, excl. 17. III - 13. IV. 1907 (Wlsm.); Las Mercedes, 2000 ft., 7. III. 1904 (Eaton); Forest de la Mina, 7. IV. 1904 (Eaton); Puerto Orotava, 15-17. IV. 1895 (Hedemann)¹, 3-14. V. 1907 (Wlsm.); La Laguna, 8. IV.

1904 (Eaton), 9. VI. 1907 (Wlsm.).

I have bred this species from *Rubus fruticosus*, amongst which it was found by von Hedemann, and Eaton. Rebel described his type as dark brownish, remarking that his second specimen, which was somewhat worn, had traces of brassy yellow colouring. Some specimens show much more ochreous spotting than the typical form, of which I have several caught and some bred specimens, in which the small yellow dorsal spot before the tornus is almost obsolete; others again, bred and caught, show three strong yellow patches on the outer half of the wing, more or less connected with each other, and another at the base of the costa. The many intermediate gradations clearly prove that these are mere variations of one species.

Tischeria longiciliatella Rbl. must not be confused with the Texan Tischeria longeciliata Frey and Boll [Stett. Ent. Ztg. XXXIX. 259 (1878), \oplus Helianthus], which Prof. Rebel probably

overlooked when naming the Tenerife species.

One specimen only of this species was met with at La Laguna, on June 7th, I have also one from Mr. Eaton, taken near the Cruz de Afur, on April 5th.

112. (2336·1) GLYPHIPTERYX FORTUNATELLA, sp. n. (Plate LII. fig. 18.)

Antennae bronzy fuscous. Palpi white, spotted with fuscous along their outer sides. Head cupreous. Thorax bronzy fuscous. Forewings bronzy fuscous, blending to brownish cupreous beyond the middle; with five distinct white costal streaks, the first, about the middle of the costa, tending obliquely outward, longer than the second, which is a little beyond it, also oblique, but not parallel, tending rather to converge; after a space, at least equal to that which divides the first pair of streaks on the costa, there follows a series of three shorter streaks, their points slightly converging in the direction of a short, white, curved, terminal incision below the apex; beyond these the cilia form a sharply uncate apex, owing to the outer extremities of those below it being pure white, while their basal halves are bronzy grey surrounding a black apical spot; the whitened cilia, after con-

66*

tributing to the subapical incision, are continued along the termen to the tornus, with their basal halves bronzy cupreous; at the tornus is a short, silvery white, triangular spot, and from the middle of the dorsum arises a rather slender, slightly curved, outwardly oblique, white silvery streak, which nearly reaches to the apex of the first costal streak above it. Exp. al. 6-6.5 mm. Hindwings bronzy grey; cilia scarcely paler. Abdomen bronzy fuscous. Legs bronzy greyish, the spurs and joints white.

Type $\c (99102)$; $\c (99103)$ Mus. Wlsm.

Hab. Tenerife: Guimar, 10–14. IV. 1907; Villa Orotava, 26. IV. 1907; Realejo, 7. V. 1907. Nineteen specimens.

Nearly allied to fischeriella Z., but differing in the middle white costal streak being always nearer to the following than to the preceding pair, whereas in fischeriella it is equidistant between them. It also differs in the more evenly slender, and more produced, oblique dorsal streak, which always reaches as far as, or a little beyond, the apex of the first costal. G. fortunatella is smaller than pygmaeella, and is common in the neighbourhood of Guimar, in the Barranco Badajos; it occurs also at Villa Orotava and Realejo.

 $(Hedemann)^3$.

Prof. Rebel (l. c. 5) records francillonana from Tenerife, on the strength of a specimen in Mr. White's collection, remarking that it was almost certainly the same as the specimen collected by von Hedemann, at Santa Cruz, May 3rd, 1895, which (l. c. 3) he had identified as *flagellana. I met with francillonana, also at Santa Cruz, in February, feeding among the seeds of Todaroa aurea, an indigenous Umbellifer. The larvae soon left the seedheads, and as I had taken no stems of the plant, when leaving Santa Cruz, they travelled restlessly round the bottles for many days after reaching Guimar: on being supplied with small pieces of *Bambusa*, and of the first *Umbellifer* I could find, they quickly gnawed their way into both of these and pupated, the moths emerging from April 17th to May 29th.

114. (1647) Loxopera bilbaënsis Rslr.

Conchylis francillana F. + bilbaënsis Rslr. Stett. Ent. Ztg. XXXVIII. 372 (1877)¹. Lozopera bilbaënsis Wlsm. Ent. Mo. Mag. XXXIV. 72–3. Pl. $2\cdot 2^{a-d}$ (1898)²; Stgr-Rbl. Cat. Lp. Pal. II. 94 no. 1647 (1901)³.

Hab. S. EUROPE ¹⁻³: ⊕ Crithmum maritimum². Canaries —Tenerife: La Laguna, 6. IV. 1904 (Eaton); Puerto Orotava, 4. V. 1907, ⊕ Crithmum maritimum, 29. IV, excl. 9. V – 17. VII. 1907, ⊕ Ferula sp., 29. IV, excl. 29. VII. 1907 (Wlsm.); Bajomar, ⊕ Astydamia canariensis, 22. V, excl. 3. VI – 19.

VIII. 1907 (Wlsm.).

Larvae found in stems of Crithmum maritimum, at Puerto Orotava, in May, produced paler and darker varieties from the beginning of May to the middle of July. I subsequently found it in great abundance in stems of Astydamia canariensis, at Bajomar, from which I reared a series of twenty specimens: a careful examination of the chitinous genital appendages shows them to be the same as in the Crithmum-feeder, and in a series of Spanish and Corsican specimens, also reared from Crithmum. A single specimen was also bred from the stems of a species of Ferula, found at Puerto Orotava. Were it not for the differences in the form of the uncus and claspers it would be exceedingly difficult to separate this species from francillonana, but the hindwings are almost invariably paler. A somewhat worn specimen taken by Mr. Eaton, at La Laguna, in April 1904, is unfortunately a 2, but I think it is certainly bilbaënsis.

Taken at Santa Cruz, in January, and at Guimar, in April—also bred from seeds of Asphodelus ramosus at the latter place, the bred specimen being much larger (exp. al. 17 mm.) than any individual of my Spanish bred series. The larvae were also observed at Puerto Orotava.

116. (1762·2) Phalonia conversana, sp. n. (Plate LIII. fig. 6.)

Antennae pale greyish. Palpi white, brownish fuscous on the outer side of the median joint. Head and Thorax white. Forewings white, with a faint subochreous suffusion, and a few sparsely sprinkled black scales, between, but not contiguous to, the dark markings, which consist of more or less thickly sprinkled black scales on a browner, or greyish brown, ground; the dark markings are as follows: an elongate streak from the base of the costa, a narrow medio-costal spot, a larger costal spot between this and the apex, with a small one beyond it before the apex; an oblique, straight, dorsal streak, of even width, terminated on the cell, and a faint shade above, forming a subcontinuous fascia with the medio-costal spot; a rather triangular dorsal spot, beyond the middle, half-way between the oblique streak and the tornus, with some dark sprinkling above it, running obliquely in the direction of the larger costal spot, and a narrow shade along the termen, followed by parallel dark lines running through the cilia. Exp. al. 9-14.5 mm. Hindwings slightly sinuate; pale brownish grey; cilia shining, silvery grey, becoming shining white on their outer halves. Abdomen pale brownish grey. Legs almost white, unspotted.

This is one of the very few species, recorded from Tenerife, which I was unable to find, although I searched on *Datura stramonium*, at La Laguna, in May and June—the time and place of its recorded occurrence.

60. (227) TORTRIX L.

I fear I may be in part responsible for the too-extended use of the geneonym *Pandemis* Hb., having placed in that genus certain South African species possessing a very faint indication of a notch at the base of the antennae: neither in these, nor in any of the Tenerife species with which I am acquainted, is there any sufficient indication of this character to justify their separation from Tortrix I might have been disposed to place them in Dipterina Meyr., separated from Tortrix L. by Meyrick on account of the presence of a distinct secondary cell in the forewings, by the stalking of veins 6 and 7 in the hindwings, and by the long ciliation of the d antennae; but an examination of Dipterina tasmaniana Wkr. shows that veins 6 and 7 of the hindwings are not truly stalked, although tending to coincidence towards the base, the secondary cell is less strongly indicated than in Clepsis Gn. (rusticana Tr.), with which it agrees in the long ciliation of the antennae. Meyrick has himself placed rusticana in the genus Tortrix, evidently regarding the ciliation of the antennæ as merely a question of degree; our Tenerife species, possessing no wellindicated secondary cell, must therefore be included in the older and more generally recognised genus Tortrix L.

Comparing the types of persimilana Rbl. (60994 $\,^{\circ}$ $\,^{\circ}$ 61000 $\,^{\circ}$: Mus. Wlsm.) with a considerable series of bred and captured specimens, and bearing in mind the examples of Pandemis mactana Rbl. in Mr. White's collection, at Guimar, I am forced to the conclusion that these names are applied to different varieties of the same species. Many of the $\,^{\circ}$ $\,^{\circ}$ agree perfectly with

Rebel's description of mactana, although paler forms, less reticulated on the under side of the forewing, also occur: there is however no possible line of demarcation between them. Some very fine fasciated QQ, with typical persimilana QQ, and typical mactana of of, were bred from larvae on Globularia salicina, at Guimar, in April and May, 12 specimens in all, including a single of bred from the same plant at Puerto Orotava. I have also bred six similar forms from Adenocarpus foliolosus, at La Laguna, in June; 1 d, in March, on Banksia rose, Guimar; 1 d, March, on Rubus fruticosus, Guimar; 1 ♀, April, on Geranium, Guimar; garden at Miramar, near Santa Cruz; 1 \, June, on Erica arborea, La Laguna; 1 ♀, April, from Jasminum odoratissimum, Guimar; 16 caught specimens make up the series of 42, to which I can add, 2 received from Mr. White, and 6 previously in my cabinet from the late Mr. J. H. Leech, and from Mr. Eaton: 50 in all.

121. (1545) Tortrix Bracatana Rbl.

Here again we have a species which varies greatly within certain limits, but is easy to recognise. It reminds one at first sight of canariensis Rbl., but the wings are more pointed, the costa being somewhat less arched, and the termen more oblique. I have bred

it from Psoralea, Artemisia, Rubus, Fagonia, Rhus, Rhamnus, Notochlaena, Astydamia, Cistus, Tamarix, Ononis, Lotus, Senecio, Poterium, Rumex, Periploca, dry aborted apples, small Cruciferae, and even from Phelipaea.

Heterognomon hyeranus Rbl. Ann. KK. Hofmus. IX. 17, 84 no. 147 (1894)¹. Dichelia hyerana Rbl. Ann. KK. Hofmus. XXI. 43 no. 185 (1906)².

Hab. Tenerife 1-2: La Laguna, V (Cabrera) 1.

I have many \mathcal{Q} of Tortrix coriacana Rbl. which greatly resemble Millière's species in appearance, and am strongly convinced that the condition of the specimen examined and recorded by Rebel must have misled him. The reference to Dichelia (when the specimen was not available for study of neuration) can hardly be held to confirm the original determination, in the absence of information as to whether veins 7 and 8 were separate or stalked in the specimen recorded. It will probably be found that hyerana does not occur in Tenerife.

Very common everywhere, and exceedingly variable, ranging from unicolorous chalk-white, through various gradations of greyish ochreous and brownish grey, to slightly, and conspicuously fasciated forms, more or less speckled between the fasciae. I bred it from Argyranthemum pinnatifidum, from Fagonia cretica, from Psoralea bituminosa, and from Stachys sp.: a series of thirty-two selected specimens was preserved, in addition to several specimens received from the late Mr. J. H. Leech, and from Mr. Eaton.

OLETHREUTINAE.

61. (247) ACROCLITA Ldr.

125. (1966·01) ACROCLITA GUANCHANA, sp. n. (Plate LIII. fig. 5.)

Antennae hoary greyish. Palpi porrect, slightly dependent, stretching the length of the head beyond it, densely clothed, especially above, terminal joint short, smooth; hoary grey, fuscous on the outer sides. Head hoary greyish, with some mixture of reddish brown scales. Thorax reddish brown. Forewings elongate, narrow, costa moderately arched, termen oblique, sinuate, tornus evenly rounded; tawny reddish brown, with some black scaling which is sometimes reduced to a few marginal specks, but in some varieties forms an elongate series of streaks or spots, more or less connected, or detached, commencing at the middle of the base, exhibited again along the cell beyond it to the apex; in one dark variety (99115) these streaks form an almost continuous line, with a diverging point along the fold; in another, paler, and faintly mottled form (99116) they are broken into three separate streaks, one from the base along the first half of the fold, a shorter one toward the end of the cell, and an outer one beyond the cell to the apex, with two minute spots below the intermediate spaces and one near the base of the dorsum; in the paler varieties there is also some indication of lighter geminated costal streaks, with alternating faint shade-spots; cilia slightly paler than the wing, with a distinctly paler line along their base, followed by parallel shade-lines running through them. Exp. al. 12-15 mm. Hindwings broader than the forewings, with oblique, sinuate, termen; grey with a slight rosy tinge; cilia paler, with a faint shade-line a little beyond their paler base. Abdomen and Legs griseous, varying to subochraceous; hind tarsi faintly shaded, except at the joints.

Type & (99115); ♀ (99118); var. ♂ PT. (99116-7) Mus. Wlsm. Hab. Tenerife: Santa Cruz, 3000 ft., 3. I. 1907, ⊕ Hypericum grandifolium, 3. I, excl. 29-31. I. 1907 (Wlsm.); Villa Orotava, 19. I did not meet with any form of Acroclita that can well be compared with littorana Cnst., which is merely a small pale variety of the ordinary South European subsequana HS. There is however one point of difference by which my Tenerife series of twenty-three specimens might be separated from European specimens: the basal patch always tends to throw out a pointed projection along the dorsum, they also range to a much larger average size (exp. al. 13–22 mm.), and I propose the neonym convallensis (var., an sp.?), to distinguish them.

Type ♂ (99171); ♀ (99172) Mus. Wlsm.

127. (1966.1) Acroclita sonchana, sp. n. (Plate LIII. fig. 3.)

Antennae hoary, with blackish annulations, sometimes entirely suffused with black. Palpi whitish, thickly sprinkled with dark fuscous externally; sometimes fuscous throughout. Head dirty white, varying to dark fuscous. Thorax whitish, or dark fuscous; sometimes with chestnut-brown tegulae. Forewings dark fuscous, sprinkled and mottled with shades of chestnut-brown, with some paler spaces; a dark basal patch, extending to one-third, projects outwardly above the fold receding to the costa and nearly to the dorsum; this is followed by an irregular fascia, running from the

middle of the costa to the dorsum before the tornus, throwing a projection inward from its middle and slightly bulging outward above its lower extremity; beyond it is a triangular shade-patch, more or less furcate to the costa, the apex and termen being also narrowly shaded; in some specimens (99110) the intermediate spaces between these markings, as well as the dorsal portion of the basal patch are white, sparsely sprinkled with brownish scales; in other specimens (99109) they are entirely suffused with dark steely greyish fuscous, paler only at the edges of the dark markings; about four pairs of geminate costal streaks are visible on the outer half of the wing; cilia fuscous, with a more or less defined shade-line along their base. Exp. al. 14-17 mm. Hindwings brownish cinereous, with a slender pale line along the base of the rather more smoky cinereous cilia; in the paler specimens the hindwings are also of a lighter shade. Abdomen and Legs corresponding to the hindwings in colour; tarsi darkly shaded between the pale joints.

Mus. Wlsm.

Hab. TENERIFE: Guimar, 7. IV. 1907, \bigoplus Sonchus gummifer, 9–27. III, excl. 4. V – 12. VI. 1907; Puerto Orotava, \bigoplus Sonchus gummifer, 23. IV, excl. 13. V – 19. VI. 1907, \bigoplus Sonchus leptocephalus, 22. IV – 11. V, excl. 5. VI – 2. VIII. 1907. Fifteen

specimens.

The larva, which is dull greyish, turning to bright red before pupation, feeds on the leaves outside the stems of Sonchus gummifer and leptocephalus. The moth is extremely variable, some specimens being almost black, on which the pattern, although easily traceable and very consistent, is much obscured, while in others all the intermediate spaces being white, the darker markings stand out very conspicuously. As compared with consequana HS., it is somewhat similar in general design, but the outer fascia is less oblique and less prominently angulated outward below the middle, while the space between this and the apex is more occupied by darker patches and the costal streaks are less confluent and less oblique.

62. (243) POLYCHROSIS $\,\mathrm{Rgt}.$

128. (1954.1) Polychrosis neptunia, sp. n. (Plate LIII. fig. 1.)

Antennae ochreous, varied with black above. Palpi ochreous. Head and Thorax ochreous, varying to reddish fuscous in some specimens. Forewings ochreous, varying to brownish ochreous, and even to reddish fuscous, the darker shades prevailing especially towards the dorsum; the costa is delicately speckled with fuscous throughout; before the middle is an outwardly oblique, greyish white fascia, somewhat contracted on the fold, terminating on the middle of the dorsum, its upper half slightly reticulated, or speckled, with the ochreous ground-colour; beyond it a narrow dark space separates it from a broad, irregular, second fascia of the same

colour, tending to become widely furcate toward the costa, and narrowly furcate where it is inverted to the dorsum before the tornus; the outer portion of this fascia is usually joined to a sinuate streak, which, cutting off the dark apex of the wing, descends to the middle of the termen; these markings all contain more or less, short, parallel, wavy streaks of the darker ground-colour; cilia varying from ochreous to greyish, sometimes slightly mottled. Exp. al. 9–12 mm. Hindwings pale brownish grey; cilia pale cinereous with a slender shade-line running through them near their base. Abdomen greyish fuscous. Legs pale brownish cinereous, the tarsi very faintly spotted.

Hab. Tenerife: Guimar, 17. III. 1907, ⊕ Frankenia ericifolia, 6. III, excl. 9. III – 22. IV. 1907, ⊕ Statice pectinata, 6. III, excl. 20. III – 18. IV. 1907 (Wlsm.); Tejina, 18. III. 1902 (Eaton); Puerto Orotava, 21. IV – 14. V. 1907, ⊕ Frankenia ericifolia, 21. IV, excl. 3–4. V. 1907, ⊕ Statice pectinata, 21. IV, excl. 26. V – 7. VI. 1907 (Wlsm.). Thirty-two specimens (13 ex Statice, 10 ex Frankenia, 9 captured).

The larva feeds on Statice pectinata and Frankenia ericifolia, at Guimar and Puerto Orotava, from both of which plants I have

bred it.

Most nearly allied, perhaps, to *limoniana* Mill., but differing in the markings being intermediate between those of that species and *botrana* S-D.

130. (1845) Rhyacionia walsinghami Rbl.

Hab. Tenerife ¹⁻³: Puerto Orotava, \bigoplus *Pinus canariensis*, 18. II, excl. 3. III − 10. IV. 1907 (*Wlsm.*), 11−14. IV. 1895 (*Hedemann*)¹, 21−29. IV. 1907 (*Wlsm.*).

A rare species, not met with by Mr. Eaton, and represented, so far as I am aware, only by von Hedemann's three original specimens, and one or two in Mr. White's collection. During a lucky half-hour, spent in the garden of the Hotel Humboldt, during a flying visit to Orotava, on the 18th of February, I found three pupae in the shoots of *Pinus canariensis*, all of which produced the moths in March and April. During a subsequent visit three other specimens were taken on the wing, in the same place, from the 21st to 29th of April. I have observed traces of the larvae in the pine-forests, to the south of Pedro Gil, but it does not appear to occur to the west of Guimar, where I searched the pines unsuccessfully.

A single specimen (13575), in poor condition, to which I wrongly attributed the name "Steganoptycha signatana Dgl." (l. c. 4), was collected in Madeira by Wollaston. Having now met with Crocidosema plebeiana at Santa Cruz, La Laguna, and Guimar, (where I also saw it in Mr. White's collection), and having bred two specimens from larvae feeding on Malva parviflora, at Puerto Orotava, I take this opportunity of correcting the previous error, while recording the species for the first time from Tenerife, and extending its range from Ceylon to St. Helena. I have examined the type of Steganoptycha obscura E. Wlstn. in the British Museum and find it to be Crocidosema plebeiana Z., a 3 with the characteristic tuft.

66. (260'01) STREPSICRATES Meyr.

§ STREPSICEROS Meyr. Pr. Lin. Soc. NSW. VI. 678-9 (1882). STREPSICRATES Meyr. Tr. NZ. Inst. XX. 73 (1887); Wlsm. Pr. Z. Soc. Lond. 1891. 506-7 (1892).

132. (2067:01) Strepsicrates fenestrata, sp. n.

Antennae missing, except sufficient of the compressed, whitish cinereous, basal joints to identify the genus. Palpi erect, with very short terminal joint; much worn, but apparently fuscous externally. Head whitish cinereous. Thorax whitish cinereous along the centre, brownish fuscous at the sides. Forewings with a very deep costal fold, reaching to beyond the middle of the wing; dark brownish fuscous, slightly mottled with whitish cinereous, tending to indicate oblique, but slightly curved, transverse lines before the apex, reaching from costa to termen, and one reaching the dorsum before the tornus, but this latter appears to form the outer margin of the more intensely dark colouring which pervades the wing thence to the base, except along the dorsum; here is a large reduplicated patch of whitish cinereous, commencing at one-fourth, indented at its upper edge about the middle, and thence extending again nearly to the outer end of the fold; there is also a pale patch at the tornus—these are slightly sprinkled with pale brownish fuscous scales, usually in the form of narrow dorsal streaks; the cilia appear to be mottled with darker and paler alternations at the base. Exp. al. 15 mm. Hindwings semitransparent, subiridescent, brownish

Proc. Zool. Soc.—1907, No. LXVII.

grey, with a conspicuous scaleless fenestrum below the base of the cubitus, reaching nearly to the origin of vein 2; cilia brownish grey. Abdomen brownish grey; anal tuft paler. Legs pale brownish cinereous.

Type & (13525) Mus. Wlsm. Hab. Tenerife: Guimar (White).

A single δ , given to me by Mr. White, is in extremely poor condition; I should certainly not have described it had it not been for the peculiar character of the fenestrum in the hindwing. It was taken from a series in his collection, which included more than one species. I certainly recognised *Crocidosema plebeiana* Z. among them, and there were others similar to the one here described.

Hab. Tenerife 1: 1905, 1906 (White) 1.

Unnamed specimens in Mr. White's collection; not in good enough condition for identification. I did not meet with the genus *Eucosma* in Tenerife.

67. (257) THIODIA Hb.

= Semasia Stph., Stgr-Rbl.

133. (1980·1) Thiodia glandulosana, sp. n. (Plate LIII. fig. 2.)

Antennae brownish cinereous. Palpi varying from ochraceous to brownish fuscous. Head and Thorax brownish fuscous above; the tegulae paler, sometimes ochraceous. Forewings with the costa evenly arched, termen slightly sinuate; ochraceous, more or less suffused with brownish, or dark fuscous scaling, the markings indicated by black patches; in an ordinary variety the wing is much mottled and traversed by sinuous streaks, the costa being streaked and spotted throughout; a strong dorsal patch is indicated, coming from the base below the fold, angulated above the fold at one-third, and produced along the more or less spotted dorsum to an obliquely erect antetornal patch of the same colour, terminating a little below half the width of the wing; in some varieties a curved band of similar blackish patches descends from the middle of the costa, bending outward through the end of the cell, and attenuated to the apex, but this is sometimes quite obsolete; a narrow blackish line, broken into spots above the tornus, follows the termen before the ochraceous cilia, which are mottled with brown and blackish above the middle and at the apex, but always with a pale line along their base; in some varieties the upper edge of the dorsal patch and the lower half of the termen, as well as the base of the cilia about the tornus, are touched with shining white, some steely grey scales appearing on the dark patch and before the apex of the wing. Exp. al. 13-21 mm. Hindwings greyish fuscous; cilia paler, with a shade-line running through them. Abdomen greyish fuscous, anal tuft and Legs inclining to ochreous; hind tarsi faintly barred.

Type ♂ (99114); ♀ (99112); var. ♀ PT. (99113) Mus. Wlsm. Hab. Tenerife: Las Mercedes, 30. III. 1904 (Eaton), 19-29. V. 1907 (Wlsm.); La Laguna, ⊕ Rhamnus glandulosa, 19. V, excl.

6-23. VI. 1907 (Wlsm.). Thirty specimens.

The larva rolls the leaves of *Rhamnus glandulosa* and is common between La Laguna and Tegeste, and in the Mercedes Forest. It is an extremely variable species allied to *signatana* Dgl.

and April, but not common.

138. (2197·2) Eucelis Marrubiana, sp. n. (Plate LIII. fig. 4.)
= *indusiana Rbl. (nec Z.).

Polychrosis? indusiana Rbl. Ann. KK. Hofmus. XXI. 37, 43 no. 195 (1906)¹.

Antennae pale brownish grey. Palpi hoary grey, sprinkled with fuscous. Head and Thorax hoary grey, with some fuscous speckling; the latter with a slight, blackish-sprinkled, thoracic tuft posteriorly. Forewings greyish white, with pale olivaceous brownish suffusion, tending to indicate two transverse fasciae, one at one-third, bounding the outer side of an obscurely speckled and shaded basal patch, the other, in the middle, accompanied on its outer side by small spots of fuscous and blackish scaling, the intermediate pale space contains a narrow fluctuate line parallel to the equally sinuate outer edge of the first fascia; beyond the middle of the wing some blackish scales are sparsely sprinkled below the middle, near the central fascia, and again in a patch between the upper angle of the cell and the apex, this patch containing three or four black dots; the termen is narrowly shaded with olivaceous brownish, a narrow black line preceding the cilia; along the costa is a series of outwardly oblique brownish streaks, of varying sizes, with more or less sprinkling of black scales, some short dark streaks also along the dorsum; cilia greyish white, delicately sprinkled and shaded with brown and black. Exp. al. 8.5-13 mm. Hindwings brownish grey; cilia shining, paler, with a shade-line near their base. Abdomen hoary griseous. Legs hoary, the tarsi spotted above with fuscous.

Type \mathfrak{P} (99051); \mathfrak{F} (99052) Guimar, Mus. Wlsm.

Hab. S. France: Monte Carlo, 1. VI. 1889 (Wlsm.)—S. Spain: MALAGA: Malaga, 29. IV – 2. V. 1901 (Wlsm.). Canaries — Tenerife 1 : 1905 (White) 1 ; Guimar, 4–25. III. 1907, \bigoplus Marrubium vulgare, 14. III, excl. 21–24. III. 1907 (Wlsm.). Nineteen specimens.

Taken, and bred; very common on the top of the hill west of Guimar. The larva feeds on the seeds of *Marrubium*, the empty pupa-cases protruding conspicuously from the dry seed-vessels of

the previous year.

This is the species which stands in Mr. White's collection, named by Prof. Rebel, "Polychrosis? indusiana Z." In appearance it is undoubtedly extremely similar to Polychrosis porrectana Z., next to which Rebel (Stgr-Rbl. Cat. Lp. Pal. II. 109), following Zeller, places indusiana. The true indusiana Z. is however quite unlike marrubiana and porrectana. Anyone seeing the type of indusiana would at once place it next to staticeana Mill., from which indeed I am quite unable to separate it, and there is no doubt that Millière's name must fall as a synonym.

The following correction should be made in the European Lists:-

(1957) Polychrosis indusiana Z.

n. syn. = staticeana Mill.

Sericoris indusiana Z. Isis 1847. 667 no. 274 l. Penthina indusiana HS. SB. Schm. Eur. IV. 232-3 no. 292 (1851), Pl. 50 353 (1849) l. Lobesia staticeana Mill. Ic. Chen-Lp. II. 430-2. Hab. S. EUROPE 1-5—Sicily: Catania, 3. VII. 1844 (Zeller) 1-2—S. France 3-4: ⊕ Statice cordata 3.

VII. TINEIDAE.

71. (435) STIGMELLA Schrank.

n. syn. = Nepticula Hdn., Z.; = *Microsetia (Stph.) Kby. (nec Stph-Wstwd.).

Type 1. Phalaena Tinea anomalella Goeze (Schrank 1802).

STIGMELLA Schrank Fn. Boica II. (2), 169 (1802).

1 (Type) anomalella Goeze [=rosella Schrank Fn. Boica II. (2). 139 no. 1890 (1802)].

When describing the genus Stigmella, Schrank inadvertently omitted to give the cross-reference to his type, which should have read thus:—

"Hieher gehört:

1. Stigmella rosella.

Tinea rosella meiner Fauna n. 1890."

It is however obvious that his remark "Ich meyne, dass die mir nicht hinlänglich bekannte Motte, welche die Rosenblätter gangweise minirt, hieher gehöre", refers to rosella Schrank (Rosenblatt G. 1890), having its "Wohnort: unter der Oberhaut der Rosenblätter, welche die Raupe gangweise minirt."

Schrank regarded his species as identical with that figured by Degeer (I. Pl. 31·13-21), to which the name anomalella was given by Goeze, and Tutt [NH. Br. Lp. I. 206 (1899)] confirms Schrank's identification. It is therefore evident that Stigmella Schrank is the oldest geneonym for species hitherto placed in Nepticula.

Type 2. Tinea aurella F. (Tutt 1899).

NEPTICULA Hdn. Ber. Vers. Naturf. Mainz **1843**. 208; Z. Lin. Ent. III. 249, 301–3 (1848); Tutt NH. Br. Lp. I. 184–5 (1899); Stgr-Rbl., etc.

Type 3. Nepticula microtheriella Stn. (Kby. 1897).

*Microsetia (Stph.) Kby., Lloyd's NH., HB. Lp. V. 313-4. Pl. 108 · 8 (1897).

Kirby adopts Microsetia Stph., sinking Nepticula Z. as a

synonym, overlooking that Westwood [Syn. Gen. Br. Ins. 112 (1840)] had cited as the type of *Microsetia* Stph., *stipella* (Hb. 20·138) Stph. Ill. IV. 265, Wd. 1347 (=Wstwd. II. 212 no. 5. Pl. 112·34)—apparently an *Aphelosetia*: but in any case *microtheriella* Stn. cannot be the type of *Microsetia* Stph.

139. (4303.1) STIGMELLA RUBICURRENS, sp. n.

Antennae steel-grey; eye-caps steely yellowish. Head black above. Thorax bronzy greyish. Forewings pale greenish bronzy greyish, a broad copper patch preceding the paler shining grey cilia. Exp. al. 4 mm. Hindwings and cilia steely grey. Abdomen fuscous. Legs steely grey.

Hab. Tenerife: La Laguna, ⊕ Rubus, 8. III, excl. 26. III. 1904 (Eaton). Unique.

This differs from fletcheri Tutt in the distinctly copper, not

purplish, patch at the apex.

Mr. Eaton bred a single specimen from a larva found mining a bramble leaf in the barranco below La Laguna, at about 1700–1600 ft., on March 8th. Mines, obviously narrower than those of aurella F., occurred on Bramble at Puerto Orotava, but I failed to breed the species. This is probably the same as the larva found by von Hedemann at Orotava, mining Bramble, in April 1895, and recorded by Rebel as Nepticula sp. [Ann. KK. Hofmus. XI. 143, 147 no. 220 (1896): XXI. 44 no. 245 (1906)]. A single specimen (99173), taken at Puerto Orotava, 14. V. 1907 (Wlsm.), is possibly a worn example of this species, but it shows only a slight coppery tint, instead of the distinct copper patch of the bred specimen.

140. (4333) STIGMELLA AURELLA F.

Tinea aurella F. Syst. Ent. 666 no. 65 (1775)¹. Nepticula aurella Tutt NH. Br. Lp. I. 228–33 (1899)²; Stgr-Rbl. Cat. Lp. Pal. II. 223 no. 4333 (1901)³.

Hab. EUROPE ¹⁻³: Rubus fruticosus ²⁻³. N. AFRICA ²⁻³—
MOROCCO: Tangier, 10. IV. 1902 (Wlsm.). Canaries—Tenerife:
Guimar, 1. III − 14. IV. 1907 (Wlsm.); La Laguna, 7–8. III.
1904 (Eaton); Villa Orotava, ⊕ Rubus fruticosus, 19. II, excl.
17–30. III. 1907 (Wlsm.).

First received from Mr. Eaton, who met with it at La Laguna; I took it at Guimar, and bred it from *Rubus fruticosus* at Villa

Orotava, where the larvae were abundunt.

141. (4368·1) STIGMELLA STATICIS, sp. n.

Antennae blackish; eye-caps pale ochraceous. Head rust-brown. Thorax and Forewings black, minutely irrorated with pale leaden grey; cilia pale leaden grey, with black speckling.

Exp. al. 3-4.25 mm. Hindwings and cilia pale leaden grey.

Hab. TENERIFE: Puerto Orotava,

Statice pectinata, 4. V, excl. 29. V - 21. VI. 1907; La Laguna, 20. V. 1907. Thirteen specimens.

Perhaps most nearly allied to helianthemella HS., but the head is ochreous, and there is no pale fascia in either sex: the antennae are long, and there is no dark dividing line in the cilia.

Bred from larvae mining the leaves of Statice pectinata: the green larva, making small, tortuous, mines in the little leaves, is fairly abundant, but very inconspicuous; the cocoon is whitish. The mines were collected at Puerto Orotava; a single specimen taken on a table in the hotel at La Laguna probably escaped from my bottles.

142. (4368.2) Stigmella sanctaecrucis, sp. n.

Antennae greyish fuscous, paler beneath; eye-caps dull ferruginous, speckled with fuscous. Head dull ferruginous. Thorax greyish fuscous. Forewings pale cinereous, profusely speckled with greyish fuscous, almost entirely obliterating the paler groundcolour, which is confined to the bases of the rather coarse scales, but shows more clearly where the scales become lengthened, as in the cilia. Exp. al. 4.5-5 mm. Hindwings and cilia very pale greyish. Abdomen greyish fuscous. Legs pale cinereous.

Type 3 (99214) Mus. Wlsm.

Hab. Tenerife: Santa Cruz, 15-17. I. 1907. Six specimens. I found this species at Santa Cruz, only among plants of Lavandula abrotanoides, on which I noticed mines that appeared to differ from those of Perittia lavandulae Wlsm. (ante, p. 971 no. 83): they were more slender, and more tortuous, and probably belonged to a Stigmella.

143. (4378·1) Stigmella micromeriae, sp. n.

Antennae grey; eye-caps silvery white. Head yellowish. Forewings steely white, profusely sprinkled with coarse dark grey, or fuscous, scales; a straight silvery white transverse fascia, at two-thirds from the base, is sometimes slightly interrupted by a few of the dark scales; cilia steely whitish, with a slight sprinkling at their base. Exp. al. 3.5-4 mm. Hindwings and cilia pale steely grey. Abdomen grey. Legs greyish.

Hab. Tenerife: Guimar, 14. III - 12. IV, ⊕ Micromeria varia,

25. II, excl. 1-9. IV. 1907. Twenty.two specimens.

The larva feeds on Micromeria varia, and I think also on Micromeria origanifolia, making small tortuous mines. It is decidedly common.

144. (4416·1) STIGMELLA JUBAE, sp. n. (Plate LIII. fig. 7.)

Antennae yellowish, delicately annulate with black; eye-caps whitish. Head bright yellow. Thorax black. Forewings white, with a broad black central fascia through which the ground-colour is visible only in small specks; a black basal patch, angulated outward in the middle, leaving only a narrow, curved, or angulated, white fascia between it and the median band, and a black patch occupying the whole apex and termen, the ground-colour showing before it in a narrow, white, rather oblique, bar, sometimes divided into two nearly opposite spots; this patch also shows some pale speckling; cilia whitish at the apex and termen, with a line of black scales running through them; greyish on the dorsum. Exp. al. 4·5–5·5 mm. Hindwings and cilia pale grey. Legs black, with white speckling.

 $Type \ \ (99119); \ \ \ (99121) \ Mus. \ Wlsm.$

Hab. TENERIFE: Santa Cruz, ⊕ Euphorbia regis-jubae, 4. II, excl. 8-17. III. 1907; Guimar, 9. III - 10. IV, ⊕ Euphorbia regis-jubae, 9. III, excl. 11-15. V. 1907. Eight specimens.

The larva makes narrow, tortuous, mines in the leaves of Euphorbia regis-jubae, and is not uncommon near Santa Cruz, and near Guimar, in February and March; like that of euphorbiella Stn., it is pale yellowish. The species is nearly allied to the South European euphorbiella Stn., but differs in the white, not creamy, ground-colour being much more obscured by black scaling.

145. (4416.2) Stigmella nigrifasciata, sp. n.

Antennae greyish: eye-caps white. Head greyish, with some white sprinkling. Thorax fuscous. Forewings white, with a smoky, ill-defined, basal patch, extending to one-third and speckled with black; a straight, rather narrower, median fascia, also thickly black-speckled, and an apical patch of the same colour including the cilia, except at their pale greyish outer ends. Exp. al. 4 mm. Hindwings and cilia pale greyish. Abdomen fuscous. Legs whitish, spotted with fuscous.

Type \mathcal{S} (99242) Mus. Wlsm.

Hab. Tenerife: Santa Cruz, 14. II. 1907. Two specimens, in excellent condition.

Much smaller and more fasciated than *jubae*, but not unlike it in colour.

146. (4418·1) Stigmella ridiculosa, sp. n.

Antennae pale fawn; eye-caps fawn-whitish. Head fawn-whitish, inclining to yellowish. Thorax fawn-whitish. Forewings fawn-whitish, profusely speckled with fawn-brown, this colour confined to the tips of the scales; cilia fawn-whitish, with very slight speckling. Exp. al. 4-4.5 mm. Hindwings very pale greyish; cilia fawn-whitish. Abdomen brownish grey. Legs fawn-whitish.

Type ♀ (99255); ♂ (99257) Mus. Wlsm.

Hab. Tenerife: Santa Cruz, 8-14. II. 1907; Guimar, ⊕ Lotus sessilifolius, 6. III, excl. 6-8. IV. 1907. Eighteen specimens.

An inconspicuous species belonging to the group of cistivoral Peyr. The larva occurs at Santa Cruz, and Guimar, mining the minute leaflets of Lotus sessilifolius. Although very minute and inconspicuous, it is easily disturbed among its food-plant, and is not difficult to breed, if the obviously-mined leaves are collected without regard to the presence or absence of the larvae.

72. (431) BUCCULATRIX Z.

147. (4246) Bucculatrix Chrysanthemella Rbl.

Bucculatrix chrysanthemella Rbl. Ann. KK. Hofmus. XI. 142, 147 no. 219 (1896) 1: XXI. 44 no. 244 (1906) 2: Stgr-Rbl. Cat. Lp. Pal. II. 219 no. 4246 (1901) 3.

Hab. Tenerife ¹⁻³: Guimar, 28. II. 1907, \bigoplus Chrysanthemum frutescens, 27. II, excl. 7. III – 7. IV. 1907 (Wlsm.); Puerto Orotava ¹, 23. IV – 10. V. 1907 (Wlsm.), \bigoplus Chrysanthemum frutescens, excl. 25–28. IV. 1895 (Hedemann) ¹.

Common on Chrysanthemum frutescens, at Santa Cruz and Guimar; I bred it from larvae and cocoons found on this plant.

148. (4246·1) Bucculatrix canariensis, sp. n. (Plate LIII. fig. 10.)

Antennae dirty whitish, transversely barred above with greyish fuscous. Head greyish fuscous, hoary whitish at the sides. Thorax whitish, thickly sprinkled with fuscous. Forewings whitish, profusely sprinkled with greyish fuscous, and with some blackish scaling; the pale ground-colour is chiefly apparent in a streak, commencing at the base below the costa and extending to the end of the cell, ill-defined, but somewhat dilated about its middle, where there is a small black dot at its upper, and another at its lower edge, some black scaling running along the fold between this and the base; there is also a sprinkling of black scales around the end of the cell, and a double line of the same in the terminal cilia; dorsal cilia pale cinereous. Exp. al. 7–8 mm. Hindwings shining, pale stone-grey; cilia pale brownish cinereous. Abdomen shining, pale cinereous. Legs pale brownish cinereous, with faintly spotted tarsi.

Type $\not\in$ (99276); $\not\subseteq$ (99279) Mus. Wlsm.

Hab. Tenerife: Santa Cruz, 11-16. II. 1907; Guimar, 28. II - 13. III. 1907; La Laguna, 9. VI. 1907. Sixteen specimens.

This species occurs at Santa Cruz, Guimar, and La Laguna, and probably everywhere where Artemisia canariensis is found; I did not actually breed it, but I found one or more larvae, and saw empty cocoons upon the plant. I have so far been unable to identify it with any known European species: it is an obscure insect, with no clearly defined markings—my specimens are in very good condition.

149. (4256·1) Bucculatrix phagnalella, sp. n. (Plate LIII. fig. 9.)

Antennae cinereous, faintly barred with fuscous. Head and Thorax whitish, the former with a strong admixture of dark rust-brown scales, especially on the middle of the crown; face and eye-caps white beneath. Forewings white, thickly besprinkled with fuscous and fawn-brown scaling; a blackish blotch, on the middle of the dorsum, is produced outward at its upper edge, and diluted in the direction of the apex, meeting, beyond the end of the cell, a corresponding shade bent downward from the middle of the costa, along which it can be traced narrowly to the base; the white ground-colour is always more clearly exhibited alongside of the darker shades and patches; apical cilia white, sprinkled with black scales, dorsal cilia greyish. Exp. al. 7–8 mm. Hindwings shining, pale grey; cilia brownish grey. Abdomen grey. Legs brownish grey.

Type 3 (99292); 9 (99293) Mus. Wlsm.

Hab. Tenerife: Guimar, 23-30. III. 1907, ⊕ Phagnalon saxatile, 27. II, excl. 24. III - 12. IV. 1907. Twenty-two

specimens, nineteen bred.

Nearest to fatigatella Hdn., but the costal shade is less pronounced, and more limited to the costa, tending to spread, not toward the dorsum, but rather toward the tornus. The larva is common at Guimar on *Phagnalon saxatile*.

73. (431.1) EREUNETIS Meyr.

EREUNETIS Meyr. Pr. Lin. Soc. NSW. V. 258 (1880): Tr. NZ. Inst. XX. 92 (1888): Pr. Lin. Soc. NSW. (2 s.). VII. 480, 562–3 (1893).

150. (4275·1) Ereunetis undosa, sp. n.

Antennae dark brown. Palpi slender, drooping; brownish. Head white, a brownish band above between the eyes. Thorax white; tegulae streaked with brown. Forewings dark chocolate-brown, with a broad white band along the dorsum, extending from base to apex, but almost interrupted at the tornus by overflow of the dark brown slightly overlapping the end of the fold; there is also a slight overlap at one-third from the base, while the white band projects a little across the fold at two-thirds; apex white, with a few brown scales; cilia white, with some greyish tinge about the tornus. Exp. al. 13 mm. Hindwings shining, pale steely grey; cilia brownish grey. Abdomen steely grey; flattened at the base, with long projecting ovipositor. Legs yellowish white; hind tibiae with long hairs above.

Hab. TENERIFE: Puerto Orotava, 2. V. 1907. Unique. Allied to seminivora Wlsm. [Ind. Mus. Notes IV. 107. Pl. 7 · 2a-d (1899)], which differs in its brown face and pale antennae.

 $(mann)^4$, 24. IV – 2. V. 1907 (Wism.).

Haworth's idionym "v-flava" has been changed to "v-flavum," despite its acceptance, with explanation of derivation, by the Entomological Societies of Oxford and Cambridge [Acc. List Br. Lp. 90 (1858)], and Stephens' genus is still written "Oinophila," although corrected to "Oenophila," by the same Societies (l. c.). Smith (Smaller Lat-Eng. Dict. 596) writes of the letter V: "V, indecl. n. or (litera, suband.) f." Haworth's idionym is therefore correctly formed, and the alteration unnecessary.

152. (4621·1) Oenophila nesiotes, sp. n. (Plate LIII. fig. 11.)

Antennae pale olivaceous brownish, with a bronzy sheen above; pale yellowish beneath. Palpi short, divergent; pale ochreous, a brownish shade on the outer side of the terminal joint. Head ochreous, with a raised rust-brown crest between the antennae; face shining, pale yellowish ochreous. Thorax ochreous. Forewings dark olivaceous brown, with two shining, pale ochreous, transverse fasciae; the first, at one-third from the base, angulated outward at the middle, the angle produced outward along the cell, forming a continuous bar reaching to the middle of the outer fascia, at three-fourths from the base, which is inverted obliquely from costa to dorsum; this median bar is continued, in a diffused and rather obscure band, from the inner side of the first fascia to the base, leaving the dark ground-colour broader above it, and narrower below it along the margins—it is also continued beyond the outer fascia, with slight interruption, along the termen and through the cilia around the apex; cilia smoky brownish grey; underside strongly iridescent, with scattered metallic scales on a bronzy fuscous ground. Exp. al. 8-9 mm. Hindwings bronzy brownish, with a few iridescent metallic scales

about the apex; cilia brownish grey. Abdomen greyish fuscous, richly sprinkled with iridescent metallic scales. Legs brownish grey, the tarsi faintly spotted with pale ochreous.

Type σ (99176); φ (99177) Mus. Wlsm.

Hab. Tenerife: La Laguna, 23. V. 1907. Twenty-four

specimens.

A single specimen of this species would certainly be regarded as a variety of v-flava Hw., but the evidence pointing to the contrary is so strong that it must at least command attention. Should it in future be decided, by someone more fully acquainted with the larval history of both forms, that they are not consistently different and separable, the name nesiotes will sink as a varietal synonym. In general appearance the new species is rather more slender and elongate—the forewings longer in proportion to their width. In markings it differs in the invariable presence of a connecting bar along the cell, between the two pale transverse fasciae: this arises from the angulate outer edge of the first fascia, and is also more or less traceable on the basal side of the fascia, where it is sometimes quite as conspicuous as beyond it. In v-flava, the angle of the >-shaped fascia is often produced outward, and is occasionally traceable as far as the second, or outer, fascia, but among all the European and British specimens that I have seen there have been none in which the central pale longitudinal bar is produced inward to the base of the wing. I brought home 28 specimens of v-flava, from various localities in Tenerife, and have 5 received from Mr. Eaton: I have also 5 specimens from Madeira. None of these possess the characters of nesiotes, although many of them were selected from a larger number of captures on account of some tendency to variation: they cannot be separated from European specimens of v-flava. Of nesiotes I have 24 specimens, all taken in one spot, about ten yards square, in brushwood under a clump of fir-trees, north of the road between La Laguna and Tacaronte, about two or three miles from the former. In that spot they were flying in hundreds: I netted twenty at a time, and could easily have taken a thousand, or more, had I wished to do so. A search for larvae proved that they must have been feeding between layers of dead leaves on the ground: there were signs of web and frass, and the moths were dislodged in plenty as the leaves were turned over, but I was somewhat hurried and did not actually find any larvae. The typical v-flava did not occur among them, nor could I find it anywhere near the spot.

dryas Btlr. ♀ (Mus. Br.).

A careful comparison of the type of rutella Z., with all the specimens of Setomorpha in my possession, shows that in the σ σ no difference can be detected sufficient to separate the five supposed species described from Caffraria, Cuba, the United States, Celebes,

and Tenerife respectively.

Busck [Pr. U-S. Nat. Mus. XXX. 734-5 (1906)] has published the synonymy of the North American form, and this must now be combined with that of our Tenerife insect. I possess a long series of rutella Z. from Sierra Leone, bred from "moss," 24. VIII – 13. IX. 1895, by Dr. W. G. Clements (to whom I am indebted for this and other valuable material); there is absolutely no difference between these and the Tenerife specimens. I have also specimens bred, in Liverpool and at Merton, from muscular fibre attached to the skull of a Hippopotamus obtained by Dr. Todd at Kasongo (Congo: 5° S.)—for these I am indebted to Mr. R. Newstead. In India the larva has been found destructive to bales of country blanketing [Ind. Mus. Notes II. 9-10 (1891): V. 201-2 (1903)], and I have a specimen bred in England, by the Rev. C. R. N. Burrows, "from moths received from Ceylon." Dr. Clements' experience seems somewhat inconsistent with these records, but it is possible that the "moss" referred to by him may have been used for packing woollen goods, or skins, or may have contained an admixture of woollen rubbish; I am however without data on this subject. I have no of of corticinella Snln. (Celebes), but this has been figured by Snellen and agrees with those already mentioned; I cannot regard this or rupicella Z. (Cuba) as distinct from rutella Z. Setomorpha tineoides Wlsm. [Pr. Z. Soc. Lond. 1886. 465. Pl. 41 · 8 (1886)], having forewings 12 veins, all separate, and hindwings 8 veins, all separate, must be removed from

Setomorpha and referred to Amydria Clms. Setomorpha grenadella Wlsm. [Pr. Z. Soc. Lond. 1897. 168–9, no. 282 (1897)] has strongly developed, folded, maxillaries and must be placed in Dendroneura Wlsm. The genus Setomorpha Z. is thus regarded as consisting of the single species insectella F., of which the synonymy is given above.

There seems little doubt that Fabricius described rutella Z. under the name insectella: in his description "postice" appears to be used in the sense of "postice" (possibly a misprint) and to apply

to the forewings.

77. (475) DYSMASIA HS.

155. (4644) Dysmasia insularis Rbl.

Dysmasia insularis Rbl. Ann. KK. Hofmus. XI. 125–6, 146 no. 184. Pl. **3** · 9 ♂ (1896) ¹: XXI. 44 no. 257 (1906) ²: Stgr-Rbl. Cat. Lp. Pal. II. 241 no. 4644 (1901) ³.

Dysmasia insularis Rbl. + instratella Rbl. Ann. KK. Hofmus. XI. 125–6, 146 no. 184 (1896) ¹: XXI. 44 no. 257 (1906) ²: Stgr-Rbl. Cat. Lp. Pal. II. 241 no. 4644^a (1901) ³.

Hab. Tenerife ¹⁻³: Santa Cruz, 8. I. 1907 (Wlsm.); La Laguna, 8. III. 1904 (Eaton), 20. V − 7. VI. 1907 (Wlsm.); Guimar, 30. III − 16. IV. 1907 (Wlsm.); Puerto Orotava, 18–30. IV. 1895 (Hedemann) ¹, 23. IV − 14. V. 1907, ⊕ in rubbish among roots, 24. IV, excl. 31. V. 1907 (Wlsm.).

Mr. Eaton made the following note on his series of *Tinea immaculatella* Rbl. and his single specimen of this species:—"Out of dead *Agave* (aloes). I believe they also breed in dead *Opuntia*." I bred a single specimen, May 31st, from a larva found at Puerto

Orotava, in rubbish among roots on April 24th.

78. (475'1) STATHMOPOLITIS, $gn.\ n.$

 $(\sigma \tau u \theta \mu \delta s = a \text{ stable}; \pi \sigma \lambda i \tau \iota s = a \text{ citizen.})$

Type Stathmopolitis tragocoprella Wlsm.

Antennae slightly longer than the forewings, simple; basal joint without pecten. Labial Palpi porrect, median joint with dense brush beneath; terminal joint as long as the median, slender. Maxillary Pulpi, Haustellum, and Ocelli obsolete. Head and face rough-haired. Thorax smooth. Forewings somewhat elongate, costa and dorsum evenly curved to apex, dorsum slightly impressed at vein 1: neuration 11 veins, all separate; 9 absent (coincident with 8?), radius subobsolete between 8 and 10, internal radial strong and acting as substitute; media strongly forked, its branches going to between 4 and 5, and 5 and 6, the latter veins somewhat approximate; 7 to costa. Hindwings with margins evenly curved to the blunt-pointed apex: neuration 8 veins; 5 and 6 stalked, rest separate; branches of media strong, to 4, and

Proc. Zool. Soc.—1907, No. LXVIII.

to stalk of 5+6, between which discoidal is obsolete. Abdomen

rather long, flattened. Legs, hind tibiae hairy.

This genus differs noticeably from Dysmasia HS. in the stalking of veins 5 and 6 of the hind wings: it would appear to have some affinity to Narycia Stph.

156. (4644.1) Stathmopolitis tragocoprella, sp. n. (Plate LIII. fig. 16.)

Antennae dark fuscous. Palpi with the median joint dark fuscous; terminal joint pale fawn, shaded with fuscous. Head and Thorax dark fascous. Forewings pale fawn, mottled with dark fuscous, the patches somewhat evenly distributed over the wing, the more conspicuous of these occurring around the margins, especially a medio-dorsal patch, with one equally well-marked at the end of the cell; between the larger spots is a sprinkling of smaller ones, those around the termen and apex throwing dentate streaks through the pale fawn cilia. Exp. $a\hat{l}$. (\vec{c}) 12–20 ($\hat{\varphi}$) mm. Hindwings pale greyish fuscous, with a purplish iridescence; cilia brownish grey. Abdomen pale greyish fuscous. Legs subolivaceous, the tarsi faintly shaded with fuscous.

Type ♂ (99094); ♀ (99095); ⊕ (99097) Mus. Wlsm. Hab. Tenerife: Tacaronte, 18. II. 1907 (Wlsm.); La Laguna, 17. III. 1904 (Eaton); Puerto Orotava, 23. IV - 12. V. 1907, ⊕ in dry goats' dung, 23. IV - 26. V, excl. 19. V - 18. VI. 1907

(Wlsm.). Thirty specimens (11 bred).

The larva, which is of a semitransparent ivory-white, with pale yellowish brown head, and with inconspicuous, much paler, pronotal plate, feeds in the old pellets of goats' dung. It is extremely abundant about the caves, on cliffs east of Puerto Orotava, and in similar situations.

Having regard to the great abundance of this insect, and to its strong superficial resemblance to Lindera tessellatella Blnchrd. (=bogotatella Wkr.), which is much more marked than in the case of Setomorpha insectella F., it seems extremely probable that Alpheraky had this species before him when recording "Setomorpha bogotatella" from Tenerife, but I have not thought it necessary to dispute Prof. Rebel's expressed opinion on the identity of the specimen which forms the subject of this bare and unsatisfactory record.

V − 21. VI. 1900 (C. W. Durrant). HAWAIIA ⁹.

This species occurred at La Laguna, Tacaronte, and Puerto Orotava, from February to June.

81. (466) TINEA L.

162. (4558·1) Тімел тоеснорніца sp. n. (Plate LIII. fig. 17.)

Antennae $\frac{3}{4}$; whitish, faintly annulate with fuscous. Palpi short, drooping, slender; greyish. Head and face rough; yellowish white. Thorax chocolate-brown. Forewings dark chocolate-brown, with clearly defined silvery white markings; first, a very

short patch across the base, then an almost straight transverse fascia, at one-fourth, scarcely broader on the dorsum than on the costa; a short triangular spot on the middle of the costa, followed by a larger triangular costal spot, before the apex, which nearly touches the outer side of a more acutely triangular dorsal spot preceding it; at the apex is a curved, narrow, white terminal band, running through the costal and terminal cilia, leaving those of the apex as a dark rounded spot within it; tornal cilia brownish fuscous. Exp. al. 7–9 mm. Hindwings pale, shining greyish; cilia pale brownish cinereous. Abdomen brownish fuscous. Legs greyish, with pale spotted tarsi.

Type $\c (14076)$; $\c (99098)$ Mus. Wlsm.

Hab. Tenerife: La Laguna, 22. II – 9. III. 1904 (Eaton); Forest de la Mina, 17–30. III. 1902 (Eaton); Las Mercedes, 30. III. 1904 (Eaton), 7. VI. 1907 (Wlsm.); Taganana, 27. V. 1907 (Wlsm.); Tacaronte, 31. V. 1907 (Wlsm.). Thirty-five specimens.

Mr. Eaton found this common on a wall, partly overgrown with lichens, at La Laguna, 22. II. 1904, and common amongst

lichen-covered trees, at Las Mercedes, 30. III. 1904.

In the \mathcal{S} the forewings are usually broader, and less conspicuously marked than in the \mathcal{P} , the pale spots and bands containing a few dark scales, therefore less purely white, and frequently smaller than in the \mathcal{P} .

163. (4575). Tinea immaculatella Rbl.

Tinea merdella Z. ?var. immaculatella Rbl. Ann. KK. Hofmus. VII. 269–70, 283 no. 50 (1892)¹. Tinea immaculatella Rbl. Ann. KK. Hofmus. XI. 123–4, 146 no. 180 (1896)²: XXI. 44 no. 249 (1906)³: Stgr-Rbl. Cat. Lp. Pal. II. 238 no. 4575 (1901)⁴.

Hab. Canaries ¹⁻⁴—Tenerife ²⁻³: Santa Cruz, 23. XII – 20. II. 1907 (Wlsm.); La Laguna, 8. III – 6. IV. 1904 (Eaton); Guimar, 13–28. III. 1907 (Wlsm.); Puerto Orotava, 19–28. IV. 1895 (Hedemann) ², 12. V – 6. VI. 1907 (Wlsm.)—Fuerteventura ¹⁻³:

Barranco del Rio Palma, 20. X. 1890 (Simony) 1.

Tinea immaculatella is by far the most abundant species in the Island; it is evidently attached to Opuntia. Mr. Eaton made the note: "Out of dead Agare (aloes). I believe they also feed on dead Opuntia." The larva probably feeds on the fibrous interior of the dead, or half-dead, stems of Euphorbia canariensis, Cactus, and Opuntia cochinelifera: I did not however observe it.

164. (4583) Tinea fuscipunctella Hw.

IV. 1904 (Eaton). N. AMERICA ⁵⁻⁶. HAWAHA ⁹. AUSTRALIA ³. NEW ZEALAND ³.

165. (4583·1) Tinea тнесорнова, sp. n.

Antennae $\frac{3}{4}$; bronzy fuscous. Maxillaries folded. Labial Palpi porrect, moderately clothed, terminal joint shorter than median, the latter with a few lateral bristles; fawn-brown, paler on their inner sides. Head and Thorax dark fawn-brown, mixed with ochreous. Forewings ochreous, thickly sprinkled with dark fawn-brown, tending to fuscous; a small black spot in the fold at $\frac{1}{3}$ from the base, another at the end of the cell, the costa and termen having a mottled appearance through aggregation of the brownish fuscous scales; in the more or less ochreous cilia are two darker shade-lines, the one near the base interrupted at short intervals, the other near their outer ends uninterrupted, but sometimes very faint. Exp. al. 11–14 mm. Hindwings shining, yellowish grey, with a brassy sheen; cilia pale bronzy grey. Abdomen and Legs shining, pale bronzy.

Type σ (98331); Ω (98336) Mus. Wlsm.

Hab. Tenerife: ⊕ in cases on walls in houses: Santa Cruz, 25. XII – 25. I. 1907; Guimar, 28. II – 10. IV. 1907, ⊕ III, excl. 29. III – 29. V. 1907; Puerto Orotava, ⊕ IV, excl. 21. IV. 1907. Thirteen specimens.

Case dust-coloured, elongate, ovate, flattened; very distinct from that of pellionella L. or allutella Rbl. It is not bottleshaped, nor visibly indented on any part of the margin, and is formed of grains of dust and woolly refuse, but is smooth and dense in texture, and is open at both ends, cleanly cut, evenly

rounded, and without ragged edges.

Differs in the plical spot being nearer to the base than in fuscipunctella Hw., also in the absence of a first discal spot above it. The more general sprinkling of dark scales causes the sub-ochreous ground-colour to be less visible, and gives it a more suffused appearance. The possession of a larval case is also a very notable distinction. Tinea fuscipunctella may be at once distinguished by having a discal spot above and before the plical.

Orotava, 13–29. IV. 1895 (*Hedemann*)², 3. V. 1907 (*Wlsm.*); Guimar, ⊕ on walls, 1. IV, excl. 2. VI. 1907 (*Wlsm.*).

Taken at Santa Cruz, and Puerto Orotava, and a single specimen bred from a case found on a wall at Guimar.

83. (441) LUFFIA Tutt.172. (4435.01) LUFFIA REBELI, sp. n. (Plate LIII. fig. 18.)

n. syn. = *lapidella Rbl. (nec Goeze).

Talaeporia (!) lapidella Rbl. Ann. KK. Hofmus. VII. 267–8, 282 no. 45 (1892) ¹: IX. 17, 88 no. 158 (1894) ²: XXI. 42 no. 122 (1906) ³. Luffia lapidella (p.) Stgr-Rbl. Cat. Lp. Pal. II. 230 no. 4435 (1901) ⁴.

Antennae \(^3\), bipectinate, pectinations commencing on joint 4, each biciliate; pale stone-grey. Head and Thorax reddish fuscous. Forewings shining, sericeous, pale stone-grey, rather coarsely mottled with greyish fuscous, the groups of this darker scaling somewhat more conspicuous along the margins than in the middle of the wing; the strongest of these groups are—one arising from the dorsum near the base, overspreading the fold, and diffused across the base of the cell toward the costa; another, arising from scarcely before the middle of the dorsum, crossing the fold and diffused upward across the cell, and two or three on the outer half of the costa; cilia shining, sericeous, mottled with pale greyish fuscous along their basal half. Exp. al. 8-12 mm. Hindwings pale mouse-grey; cilia slightly paler and more shining. Abdomen pale mouse-grey. Legs pale stone-grey.

Type σ (99066); φ (14094) Mus. Wlsm.

Hab. Canaries ¹⁻⁴ —TENERIFE ¹⁻⁴: Las Mercedes, 2100 ft., 29. II. 1904 (*Eaton*); La Laguna, 15. III. 1902, 16–25. III. 1904, \oplus in cases on walls and rocks, 22. II − III, excl. 23. III − 10. IV. 1904 (*Eaton*); IV. 1885 (*Leech*) ²; Puerto Orotava, 23. IV. 1907, \oplus on rocks, 24. IV, excl. 10–20. VI. 1907 (*Wlsm.*); Pedro Gil, 1300–1500 m., 30 VII. 1889 (*Simony*) ¹. Seventeen specimens.

This is the species recorded by Rebel as "lapidella Goeze," but it is a much larger and more distinctly marked species. The small cylindrical cases are extremely abundant on walls, and rocks, at Santa Cruz, Guimar, Orotava, and La Laguna, but unless obtained about the time of pupation, when through want of movement they can scarcely be distinguished from the numerous empty cases of previous generations, the larvae are very difficult to rear. It is almost impossible to keep a supply of small lichens, such as they feed upon. I first received this species from the late Mr. J. H. Leech, who took it in April 1885; Mr. Eaton took several specimens, and bred three σ and two ρ in 1904. There may possibly be some allied species in the Island, but I only met with rebeli.

	Trichotaphe convolvuli (Type ♀ 99004)	
	Chersogenes victimella (Type of 99008)	
	Ambloma brachyptera (Type of 99007)	

TENERIFE MICROLEPIDOPTERA.

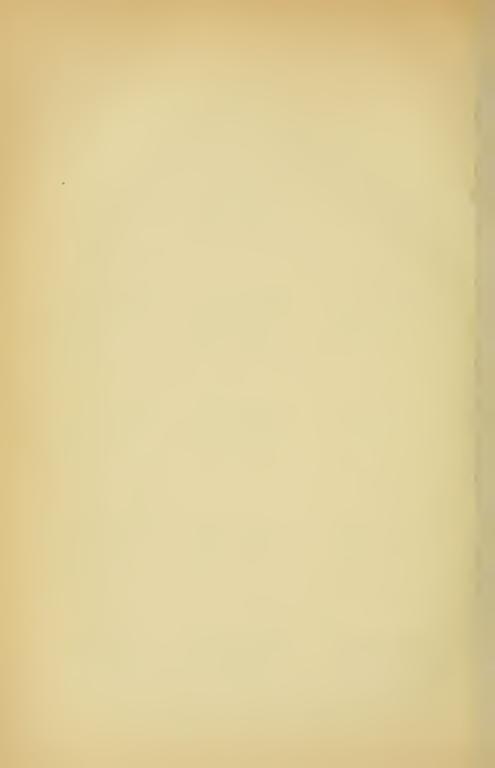

PLATE LII.

DESCRIPTION OF PLATE LII.

	Page
Fig. 1. Symmoca canariensis Rbl (& 99101)	949
2. Symmoca aegrella (Type ♂ 99009)	949
3. Apatema lucidum (Type & 98242)	945
4. Blastobasis velutina (Type ♂ 98258)	952
5. Prosthesis exclusa (Type & 98291)	953
6. Zenodochium polyphagum (Type & 98227)	954
7. Agonopteryx cinerariae (Type of 99011)	955
8. Agonopteryx perezi (Type of 99018)	957
9. Depressaria tenerifae (Type ♀ 99020)	
10. Cosmopteryx coryphaea (Type of 99029)	964
11. Aphelosetia hypoleuca (Type & 99036)	968
12. Perittia cedronellae (Type ♂ 99047)	970
13. Polymetis carlinella (Type & 99037)	
14. Mendesia symphytella (Type ♀ 99045)	
15. Scythris fasciatella Rgt (3 CT. 99087)	
16. Scythris arachnodes (Type of 99082)	
17. Scythris petrella (Type & 99085)	
18. Glyphipteryx fortunatella (Type ♀ 99102)
